So you think that 1000 users at your location were always using ARPANET simultaneously? Please don't tell me that someone gave you an engineering degree, because you obviously didn't understand the course work.

Comer's books on TCP/IP are standards, and they don't involve a wiki. They happen to be in my library of reference textbooks, and they happen to be standard references kept in all university libraries.

The claim about slow speeds on ARPANET and Usenet is quite stupid. ARPANET and Usenet did not exist at the same time. ARPANET didn't use TCP/IP protocol, and it gave way to what is now called the Internet when TCP/IP became the standard packet delivery protocol. Shortly after that, the message posting system called Usenet was formalized to run on the Internet and on several other message delivery systems (such as UUCP). So your reference to ARPANET is simply irrelevant. ARPANET and Usenet never coexisted, making the claims about 300 bps and other speed limitations total BS intended to impress the ignorant.

Enough said. Conversation ended. You don't seem to be worth any followup messages until you do some additional reading.

Anybody ever tried connecting both sections of the valve together and
using this device on HF instead of VHF? Its cheap and is good for 100W
max output with 1kV anode potential.

From: Chuck Harris on Sat, Oct 7 2006 12:40 pm

   Thank you for the explanation. As a user on a corporate system
   (RCA Corporation, EASD, Van Nuys, CA) '73 to '75, and with a
   Tym-Share account (the time-sharing computer company), I concur.

   Heh heh heh...the "high tech" of its time, a mere 30+ years
   ago. "Speedy" Teletype Model 33s (?) and "high speed" 300
   baud video terminals (with local memory to print out screens
   on Teletypes) where I was using it. :-)

>> 300 baud, my ass! You should have been on a time sharing machine

"Concentrators" still exist but in a vastly different form,
configuration, and specifications. As a personal computer
hobbyist since '76 I've not delved into them (no need to for
personal dial-up connections) but know many who are; they
have supplied some interesting literature on them as well as
in-person explanations.

>> so don't bother to backpedal by

HAAAAAA... :-)

Blowcode has never stated his amateur license call. Perhaps
he has "forgotten" it? :-)

SolderSmoke!
A SHOW FOR ELECTRONICS HOMEBREWERS!

http://www.soldersmoke.com

Listen at: http://www.soldersmoke.com

SolderSmoke #34 (October 7, 2006) is now available on http://www.soldersmoke.com

Ashhar Farhan joined us from India for #34:

-- BITX-20 transceiver.
-- HB in India.
-- EMRFD.
-- W7ZOI influence.
-- Hans Summers.
-- Quadrature rigs.
-- DSB and PSK31.
-- Homebrew test gear.
-- The importance of measurement
-- Farhan's 'scope.
-- Homebrew heartaches.
-- Homebrew spirit.
-- Symmetry.

Tired of listening to Led Zepplin or NPR on your I-Pod?   Wouldn't you like to be able to carry with you the kinds of ham radio conversations that you listen to while in your radio shack?
Mike, KL7R, in Juneau, Alaska, and Bill, M0HBR, in London, England meet regularly on the ECHOLINK system to discuss their homebrew radio projects. We are making them available as PODCASTS.

RSS FEED: You can subscribe to the program, have them downloaded to your MP-3 player, and listen to them at your convenience. To subscribe, just cut and paste this URL into your I-poder (or similar)

software.
http://www.soldersmoke.com/soldersmoke.rss

If you don't have an MP3 player you can just go to the
site below and listen to the latest program (and
earlier editions) using the audio software on your
computer.

http://www.soldersmoke.com

All our programs are available here.

We hope you enjoy the program. Please send us
feedback.

73 from London

know his for certain? no i don't but it seems likely it is K4YZ or at
least one of his close freind from years past here on RRAP but Slow
code to much of a coward to say what his call is

amusing that K4YZ does not pund on him or Arf arf for being no calls
make it realy likely he knows who they raly are

Not a good idea. This dual tetrode is internally neutralized for push-pull operation (the little crossover "twigs" above the anodes) but in a parallel connection that same capacitance will appear as unwanted anode-grid feedback.

> Its cheap and is good for 100W
>max output with 1kV anode potential.

The QQV06-40A is not capable of a clean 100W output on SSB! Many have tried over the years, and all have either failed or become extremely unpopular on the air.

If you want higher power at low cost, go for a GI-7B triode.

```

For a quickie CB antenna, a vertical dipole (1/2) wave can be made right from the coax itself You take your coax and very carefully, without nicking the braided shield, strip 102 inches of the outer insulation jacket off one end. After removing the outer jacket, start bunching the shield down the coax from the end. Now, where the outer jacket and the shield meet, separate the braided shield enough to get the inner conductor out through the hole in the braid. Pull all of the inner conductor through and stretch it and the braid out. Be careful not to skin any of the insulation off the inner conductor. Now attach an antenna insulator to the end of the inner conductor. Measure the braided shield. Cut it off at about 106" and attach an antenna insulator to the end. The total length of the inner and outer conductor should be about 17 feet (1/2 wave). You can haul it up to any height you want with a string or rope attached to the insulator on the center conductor. It's a good idea to coat the end of the coax cable where it separates with some kind of waterproof sealer. This keeps water from seeping into the coax, which could cause a high SWR.

Just attach a coax connector on the end of the coax going to your transceiver and you are on the air. The SWR should be 1.5 or better, if cut to the proper length. It'll get out about as good as a =BC wave ground plane CB radio antenna if you get it up high and in the clear. Do not hoist this antenna up next to a metal pole, because the metal will interfere with the antenna's operation and cause a high SWR

just get the lenght's right and you can mount this to a NON conducting pole eg wood , plastic coated carbon(fishing pole)

Just because you can find the names of some books by using google, doesn't
mean you have ever read them, or understood them. I have copies of all three
volumes of "Internetworking with TCP/IP- Client -Server Programming and
Applications" by Douglas E. Comer, and David L. Stevens, Prentice Hall on
my book shelf. (pick a page, any page, and I'll give you a quotation from it.)

If you note the copyright date of this series, you will see 1993. A mere
20 years after I started working with GE's world wide networks... top posting
my email on model 33 teletypes with bell 103 modems.

>
> The claim about slow speeds on ARPANET and Usenet is quite stupid.

Really? Well, I suppose you think that everyone had 56K connections back in the '70's. I worked in the Electrical Engineering department at the University of Maryland, back then, and we were pretty proud of our first 9600 baud connection between the PDP11's, and the Univac's that had the darpa connection. It wasn't until we got a VAX 11/780 that we got a 56K pipe to the Univac's that connected to the darpanet. That was around 1980. I think diapers were you most prominent media for communication back then.

> ARPANET and Usenet did not exist at the same time. ARPANET didn't use
> TCP/IP protocol, and it gave way to what is now called the Internet
> when TCP/IP became the standard packet delivery protocol.

Prior to usenet, a variation on email, we were using email broadcast lists. The same top posting rules applied.

Usenet came into being while I was in graduate school, around 1980-83. I remember there was quite a buzz at that time. Decwriters were 300 baud, and the most common affortable modems were still using the Bell 103 standard from the late '50s. 1200 baud modems were used for expensive applications, usually computer to computer data transfer. The 1200 baud modem didn't come into general use until DC Hayes produced an inexpensive model around 1983. It was a real screamer compared to the Bell 103's.

Shortly
> after that, the message posting system called Usenet was formalized to
> run on the Internet and on several other message delivery systems
> (such as UUCP). So your reference to ARPANET is simply irrelevant.
> ARPANET and Usenet never coexisted, making the claims about 300 bps
> and other speed limitations total BS intended to impress the ignorant.
>
> Enough said. Conversation ended. You don't seem to be worth any
> followup messages until you do some additional reading.

I don't need to read about it, I was there doing it. My first exposure to a world wide network was GE's back around 1970. It was the first commercial use of a global network. The normal terminal to connect to that net was a Model 33 Teletype, with a bell 103 modem. I bet you think they used Windows based PC's with 56K modems, and Netscape.

Thanks Paul for the long explanation!

I don't found a good source how ferrite rods works for transmitters. All say it cannot work because of big power eating in the ferrite. How much power is possible?
I think 1 watt should be possible.
I google on...

> >http://www.ancom.no/
> >products? They claim their ferrite rod styled antenna works as good
> >transmitter. See their patent application.
>
> These seem to be near field devices even at MF, where they seem to
> operate.

No! They are far-field devices.

I even saw a explosion picture of a mobile phone antenna 900MHz helix construction as composite in a (ferrite?) filled outline.

Does an antenna exists, which receives BOTH field-vectors? If the antenna covers only one /E or M), half of the transmitting power is lost - correct?

- Henry

Hello John. I'm KB9RQZ, and I just love CW. We need to bring back code testing for Techs. 13 wpm should work fine, Then we can keep the riff-raff off the repeaters and end all the bogus moon bounce contacts.

I've been burned by bogus EME contacts, but I'm a retard.

I haven't forgotten it. It's a real 20WPM extra class licence. Not one of
them cheap Nickled down hand-out ones. Heee Heeee Heeeeeeeeee.

Ten-Four Len?

I already received a reply from your service provider, but I'll send this to
them also.

As to gay bashing.... You are a liar.  You can't find a post anywhere to
support your lie.

"What do you like best about appliance operating?"

The are wonderful for making dinner, washing the dishes or washing or drying clothes.

Hey Mark, this retard is following you around and harrassing you.  You
should complain his ISP about him and dont let the bitchwhore get
way with it.  He also violate his state laws and you state laws and
you can file police complaint against the harrassment coward.

Hi Tom,

"K7ITM" <k7itm@msn.com> wrote in message
news:1160168316.507130.68170@m7g2000cwm.googlegroups.com...
> Sheesh, indeed. Where did you hear _that_?

Various people at Tektronix. Perhaps they were trying to portray Agilent as being somewhat more "shrunken" than they really were based on how downsized they'd just been?

The new Agilent MXA series analyzers look really nice (we've had a demo). I'm glad to see that the Agilent spectrum analyzer folks realized that, if you're going to have an instrument that's based on a PC architecture, people want a *good* PC architecture to back it with -- I'm thinking of the MXA's XGA LCD, some reasonably modern CPU, etc.; it's *snappy*. Compare to some of Agilent's network analyzers... we have an N5230A that's only 9 months old, and it has a 640x480 LCD *with a dead pixel* and a whopping 500MHz CPU. Ouch! My understanding is that the current ones still have the same old LCD, but a 1.1GHz CPU now (woo hoo!)

Thanks for the extra information,
---Joel

All the crotchety old farts are either off somewhere beep-beep-beeping
away on CW or bitching to each other on the lower half of the 80m phone
band, so it's easy to avoid them and talk to someone who enjoys ham
radio as it is instead of whining about how it was.

Good riddance! Both John and Karl whose bellicose, fragile egos contributed to the ruin of QRP-L by chasing off brilliant contributing engineers and operators then ultimately forced the exile of QRP-L from its home on listserv.lehigh.edu . Cheers to QRP-ARCI with exercising their Freedom of Disassociation and dumping Beavis-n-Butthead!

AMERICA IN DANGER   of its own   out-of-control   Bio-Terror:
               Is 1984 here? Or cripping...   God help us,
blinded!
Originally Secret Bio-Aerosols are misused to HARM and Torture in
U=2ES.A.
Tempering with pills/ medicine/ treatments to HARM and DISABLE !

       Our government needs TORTURE in U.S.?   See details
below...
       It has your VOTE, support?   Abused...   for power-grab or
vicy-terror!
       Transitory harm and HELL are U.S.-legal?   for
critics-cleansing.

       Did Denny Hastert cover the basterd? And other Washington
crooks?

CRITICS (political/social/cultural) are harassed and secretly persecuted
along with their KIDS in schools/colleges, especially, during tests/exams
(Think: Guantanamo "stress-positions" in the context of 1984-technologies)
Female FBI-informers are coerced and abused!

Bio-Aerosols and aerosolized chemicals are used to cause:
- severe colds/coughs turning into bronchitis, eye irritation
- bacterial pneumonia/other pneumonia, shortness of breath
- surges of severe headaches, migraines, dizziness, etc.
- fainting collapses by symptoms-mimicking aerosols
- severe stomach pains (sharp, burning, nausea, etc)
- chest-wall pains, heart-muscle inflammations/trauma, etc.

WORSE:
- heart attacks under cover of second-hand smocking
- aerosolized chemicals from the death-penalty drugs
- car crashes/accidents by Vertigo-causing aerosols
- car accidents due to the fine/controlled tempering
- liver/organ failure by small-dose toxins (trace-less?)
- cancer-causing/facilitating - months-long assasinations

This "Yushchenko syndrom" CAN destabilize NATIONs
Waste, Fraud, Cronism and Abuse in HomeSec/FBI
Fabrication of Believable Info/Manufacturing of accidents

U=2ES. mail IS polluted in "anthrax-like" manner to HARM critics
Libraries, airplanes, hotels, offices, buses, trains - all polluted!
Remote control, off-jacket/off-book/off-paper pollutant attacks!

A network of Secret Gas-Aerosol Rooms operated in US
(in Philadelphia, Narberth, Lower Merion, PA)
(in Wilmington and Newark, DE)
(in Hampton, Williamsburg and Richmond, VA)
AND ELSEWHERE.... details below...
Freddie May/Freddie Mac likely used to buy silent cooperation
Bio-aerosols used to hurt and simulate panic attacks, etc.!
Soviets locked critics into nut-houses, now WE do the same!
Symptoms-mimicking aerosols do HARM, weak or ill people.

Echo-location/wire-taps/listening used to turn homes into cages!

Say "Stop, I care" - call Senate (202) 224-3121
House of Representatives (202) 225-3121
What IS going on in America? *Print and Post*
Manufacturing of FEAR to grab more Power and Money, of course.
Tragedy IS used to Power Graib, while Fear is molded into profit!

Big Brother spins protection...
And fear is used to clamp.

Democracy needs action!
On which side do you stand?

Looked at this?!! Go to Google/Yahoo newsGroups:
---=

TORTURE IN USA: Secret Aerosol Rooms

US Scientist needs legal help dealing with the secret aerosols rooms (SARs) operated illegally in Philadelphia area, Newark (DE), Hampton and Williamsburg (VA) and other places. Highly volatile aerosols with and without bacterial content cause dry cough, airways a...

Full text was at:
http://buyit.philly.com/findit/search/results.jsp?catId=3Dkrd_philenqda...

This was a new on-line ad placed in Philadelphia Inquirer and Philadelphia Daily News on www.philly.com (see full text below)
It was about the secret aerosols rooms in US. One could find it by searching "secret", say, in the ad section of philly.com.

Democracy can not function effectively without the informed public. As a former NASA Langley scientist working in the area of nanotechnology and nanoscale particles, I have been recently exposed to the establishment of secret gas-aerosol rooms inside of United States, at least in the Mid-Atlantic region (from Philadelphia to Virginia). First, the highly irritant aerosols have surfaced at the NASA Langley Research Center in several safety accidents. Investigations were blocked, probably, because of lack of Congressional approval for such financially-lucrative research at NASA. Later, these aerosols had been encountered outside of NASA in Virginia, Delaware and Pennsylvania
.
This points out to yet another proliferation of originally-sensitive technologies into domestic American life to hurt and harass people without a proper oversight and much control. This amounts to torture, extra-judicial prosecution and authoritarian intimidation tactics. The use of such irritants and the operations of the secret gas-aerosol rooms are gross violations of human and constitutional rights of American citizens and various domestic and international laws.

-------------------Full text of an ad from Philadelphia's philly.com-------------------------
TORTURE IN USA: Secret Aerosol Rooms
US Scientist needs legal help dealing with the secret aerosols rooms (SARs) operated illegally in Philadelphia area, Newark (DE), Hampton and Williamsburg (VA). Highly volatile aerosols with and without bacterial content cause dry cough, airways and eyes irritation, chest pain and inflammation. FBI and Homeland Security associates are likely operators of SARs, while collaborators may be hotel staff and landlords, who get financial/material or other incentives. US citizens and kids are victims.

Torture is any act by which severe pain, whether physical or psychological, is intentionally inflicted on a person as a means of intimidation, deterrence, revenge, punishment, sadism, or information gathering. At times, medicine and medical practitioners have been drawn into the ranks of torturers, either to judge what victims can endure, to apply treatments which will enhance torture, or as torturers in their own right. http://en.wikipedia.org/wiki/Torture

America in Danger!

America in danger -
The vice is NOT impeached.
America in danger -
The public trust is breached.

Big Brother spins protection
And fear is used to clamp.
Democracy needs action!
On which side do you stand?

Which side are you on, boys?
Which side moves you on?
Which side are you on, girls?
Which side did you wrong?
(Chorus after F. Reece)

Your church is burned by haters.
The priests to go to jail?
Your dreams are cheyned by traitors,
But hope still shines through veil.

Dust rooms came back to gas us
With neo-Naz (or Con) embrace...
New immigrants do make US!
And not the SSuper-race...

***

The Government of Torture

Our government needs TORTURE?!
It has your VOTE, and, now, support?
But peace (not vice) needs steady nurture
And trustful words of calm rapport.

Beware of loud, but FALSE, ideas
That flame a thirsty hellish torch.
Protect the old and true ideals
And Constitution's civic urge.

Yes, torture IS a hellish torch -
In bloody hands, a blinded sword,
With Constitution used to forge
All laws on rights as mere absurd!

Remember victim's silent cry
And SEE the Christ in all of us.
Don't let your government to spy
And torture with some bio-dust.

There is NO good use for evil torture!
No matter how the need is spinned
By Nixon's men, as bloody sergeants,
While truth is painfully re-skinned.

V. Haryk-Bukovynsky =A9 VMH

I am wondering what's the bad effect of cascading a lot of low noise
amplifiers? It seems that if I devide 90dB into 4 LNAs I will have much
less noise figure. Can I use 5 LNAs in series? Any disadvantage about
this way? Thanks.

If your 1st LNA has the lowest noise figure and sufficient gain, it will set the noise floor.
You can work the cascaded amplifier equations and see what you will need.
90dB seems like a LOT of front end gain- unless this is very narrow band, I would be very concerned about overload resulting in all kinds of in band garbage.

What do you mean by overload? How come there is too much garbage as long as my NF is low?

I actually need 143dB gain. What kind of problem I will have if I just use 6 stages of amplifiers, like 1stage(20dB, NF2.4dB) 2nd stage(30dB, NF3db), 3rd stage(43dB, NF 6.2dB), 4th stage(43dB NF6.2dB). It seems my NFtotal is pretty low. What's my problem?

Thanks.

Your problem is you don't know what you're doing.

What frequency is this oscillator going to run at?

I asked what I don't know. I am expecting a helpful answer.

The frequency is 70MHz.

Basically, with 20 dB of gain, your noise figure will be well established with the NF of that first stage of 2.4 dB. It will actually deteriorate a tenth of a dB or so for the further stages down the line, but not very much. The second stage could have as great a noise figure as 10 dB and the total would only deteriorate to 2.62 dB

If you need additional gain, it's best obtained after some selectivity. 140 plus dB of gain on a single frequency is going to be VERY difficult to tame and keep from oscillation in it's own right.

It seems that I know the Friis equation.

I am asking because it seems difficult, and maybe impossible. I've
never heard of this high gain before, but I dont' know why I cann't
stack amplifiers and I am looking for somebody who can tell me what
exactly the problem is: you see the NF is nice, and I can get the SNR
if the band is narrow enough.

It also seems that I "don't know what I'm doing". So please explain a
little if you want me to understand. Thanks.

It sounds like you run a lot of 11m, not surprising considering how much
you whine, and it's not alternator whine.

Well, how about a little additional information? What is it that you're trying to accomplish? A gain of 140 dB would amplify a signal of strength 8 x 10^-10 Watts (About the equivalent of a received signal of 10 dB over "S"-9) to a kiloWatt. I don't think you're trying to do that, so what convinces you that you NEED 140 dB of gain?

Regards
W4ZCB

I'm dealing with a DSSS current signal at 70MHz. Before I start designing anything, I am calculating the signal amplitude. It's going to be 5nArms. If I have a 50ohm resistor, it's -153dBm. I'd be happy to know any solid proof that it's not doable because it's my job now.

In theory DSSS signal can work under noise level, but can it be so much?

I googled and saw GPS signal is -150dBm. So it's detectable, but it's
much higher frequency. What if it's 70Mhz?

Well, I have no idea of what a DSSS signal is, so I can't be of much help. Whatever it is, it better be in a very narrow bandwidth. At that signal level, it will take a 50 Hz bandwidth to achieve minimum discernable signal (MDS) with a front end NF of 2.4 dB.

If you're talking about using autocorrelation to bring it up out of the noise, all bets are off depending on how much time you can sacrifice.

If you're planning on bringing this signal to -10 dBm, better prepare for a lot of shielding and decoupling, not to mention filtering and frequency stability at 70 MHz center frequency.

Well, the GPS signal is detected all right, but they sure don't put all
their gain at the signal frequency.

It probably isn't going to make a lot of difference whether it's 25 cm. or 40 cm; the principles are the same for DSSS decoding.

GPS signals make heavy use of PN sequences so that they can be detected using autocorrelation techniques. They're down below the terrestrial noise threshold, and require autocorrelation techniques for synchronization and detection. But you probably know that already. This probably will be true of your solution as well, and especially so at those power levels.

If you're going to be receiving and detecting signals at those power levels, you'll need to use something other than *just* amplification to pull the modulation out.

One presumes you'll have a known short spreading sequence that you can use to try to sync up on the signal, or (if it's a longer sequence) that you'll have a rough idea of the code epoch, so that you can try to sneak up on it from behind, as it were.

The point here is that a _lot_ of the process gain comes from the autocorrelation and despreading processes. You may not need all that analog gain. Getting it up to ... something like -30 dBm or -15 dBm may be enough -- or even overkill.

Some comments:

DSSS is direct sequence spread spectrum. It is wideband on the front
end.

It is probably not a valid comparison to compare DSSS detection levels
with GPS. GPS encodes much redundancy into the signal to enhance S/N,
and unless the DSSS encoder does something similar we can't use the
same detection level numbers. To say DSSS works under the noise level
assumes some gain due to encoding, and probably also assumes an
information bandwidth much less than the spread spectrum bandwidth.

Here are the main reasons you can't cascade a lot of gain at the operating frequency. Others have mentioned this--so this is just a summary with clarification:

1. Stability. A lot of gain at a single frequency is difficult to do without causing stability problems. Even careful shielding between stages doesn't`always work. At 70 Mhz, about 40 dB is the best I can do reliably and even then I would use two separate metal enclosures, each with 20 dB of gain. Above, say, 60 dB all kinds of things go wrong--enclosures don't shield well enough, power supplies don't decouple enough, interconnects talk to each other, etc. With single-chip MMICs and LNAs it's really easy to build something and see for yourself.

2. Intermodulation and blocking. Any unwanted signal at the antenna would be amplified--assume you are trying to detect a -150 dBm signal and someone in the house has a wireless headphone, which transmits at about 72 MHz. With 140 dB of gain your amplifiers would saturate completely and pass none of the wanted signal.

Radio design uses a careful balance between gain, mixing, AGC and filtering to minimize stability and overload problems. For narrowband signals you want to apply selectivity as soon in the signal train as you can. For spread spectrum you do the same: a filter as narrow as you can get it and still pass the spectrum, then your despreader at the lowest level you can make it, then a narrow band filter that just passes the information, and finally more gain and the detector.

3. Components
  Some components such as crystal filters and mixers work better at lower signal levels before a lot of gain is applied. This is really just an extension of reason 2.

Hope this helps.

Well, I may have to go back to the old question, because it's not
exactly a DSSS depending on cross correlation. What are the possible
bad effects when I keep connecting amplifiers? Shorter bandwidth?
Smaller IP3? There should be something I don't know.

>
>Boltzmans constant times temperature

KT for any resistor at room temperature =-174 dBm/Hz. That's as good as you get without cryogenic cooling.

Add 17 dBm to increase bandwidth from 1 Hz to 50 Hz = -157 dBM/Hz

Add 3 more to get to MDS and it's -154 dBm, your signal level.

While you are being all holier than thou, what did you design and build for your main rig? I'm hoping to be impressed, but expecting to be disappointed.

Did the code help you with the design?

I took my Advanced class test down at 1919 M street 36 years ago. I had to sit at the desk and copy one solid minute out of five error free at 13WPM. I passed it on the first try. I almost failed the sending test, as I had never spent much time doing that. I had never made a code contact before my test, and I have only made a couple since.

The thing about code contacts is they never seem to want to say anything beyond:

WA3XXX DE W6XX RST 5NN WX FB 73 W6XX SK

How does that help the cause of amateur radio?

I have designed and built numerous rf receivers and transmitters, many are employed by the US Army for various uses. I have fixed many different radios from tube stuff through DSP driven affairs.

How exactly did the code help me to do this?

For me code was a means to an end. I wanted my license, so I learned the code.

There were plenty of rude, profane, and generally unpleasant hams on the air back when all had to pass the test in the offices of the FCC. I haven't noticed that things are any worse now. About the only real difference is in the quality of the gear folks are running. It is much better than the crappy stuff that was on the air back in the early 70's.

The problem was, you got some prior answers and then wanted to argue about it.

>
>The frequency is 70MHz.

Then, assuming some type of filtering around that frequency that's more or less where your system will likely oscillate.

One reason superhetrodyne receivers were developed to replace TRF receivers was to develop system gain at different frequencies so as to minimize the chance of oscillation. Another, of course was to achieve better selectivity that with older technology was better accomplished at lower frequencies.

Even a single conversion receiver usually develops its gain at three different frequencies: r-f, i-f and post detection.

On 11 Oct 2006 13:33:26 -0700, Lathi.Tan@gmail.com wrote:

>I'm dealing with a DSSS current signal at 70MHz. Before I start
>designing anything, I am calculating the signal amplitude.

You did not specify the chip rate or base band bit rate and spreading function. For GPS signals the chip rate is 1.023 MHz, and the signal spectrum is about 1 MHz wide, so the front end selectivity should be as close to this as possible.

For a terrestrial 70 MHz DSSS system, there are usually going to be several independent DSSS transmitters sharing this 1 MHz bandwidth (or whatever your chip rate is), some being close to the receiver and some very distant.

If you want to receive the distant signal and use the whole 1 MHz bandwidth all the way through the 140 dB gain, a weak distant transmitter producing only 0.1 uV at your receiver antenna terminal would be amplified to 1 V. However a local DSSS transmitter sharing the same 70 MHz band with a different PN sequence could produce 1 mV at your antenna terminal, which should also be amplified by 140 dB to 10 kV, which clearly is impossible ! The strong signals would saturate the later amplifying stages and the weak signal would not get through.

A reasonable gain/bandwidth distribution for a 70 MHz system would be to use a low loss band pass filter with a few MHz bandwidth at 70 MHz, to take out any VHF band I TV signals and FM broadcast signals at 100 MHz. Use a low noise amplifier stage, followed by a filter with deep sides which is matched to the bandwidth of the service (1 MHz for GPS). Then perhaps one stage, possibly with AGC and then the despreader, followed by a filter matching the bit rate (not chip rate) of the signal, followed by multiple AGC amplification stages to amplify the despread signal before the actual BPSK or whatever detector.

In terrestrial systems at 70 MHz the noise temperature is well above 300 K, thus the antenna noise figure is much worse than 3 dB, so trying to keep the receiver system noise figure below 3 dB might not be too productive. It might even be better to suffer an additional 1 dB noise figure hit and use steep filters tailored to the chip rate in front of the first LNA.

When the answer is not clear for our doubts, we argue about it for better explanation, until the doubts are solved. I think this is a healthy way to get answers.

2.3GHz is not too far from the frequency of a microwave oven.
Zap it and you will find out. It might be a good idea to
put a cup of water in the microwave with it.

Hi

I wouldn't try perspex nowadays
Perspex itself is very lossy when compared to modern compounds
I think perspex absorbs easily humidity and then you may have problems.
Specially in voltage maximum points of helical.
For the same reason I don't recommend fiberglass for outdoor use.

I recommend Teflon or nylon for insulators and supports.

I have read that toothbrush handles work very well. I'm not sure how you
would use them to mount a helical antenna, but with it in front of you,
it might be easier to figure out.

73,

Geoff.

Wow, I'm amazed you put Teflon and nylon in the same category! There
are many types of nylon, and AFAIK, none is particularly low loss.

One reference I have suggests a dissipation factor for polymethyl
methacrylate (unadulterated "Perspex") of about .008 at 3GHz. Nylon 66
(a common formulation) seems to be about three or four times that much.
 But beware that you commonly don't get "pure" plastics.

For comparison, Teflon runs more like .00015 dissipation factor at
3GHz. Pure forms of polyethylene and polystyrene are similarly low.
Polypropylene tends to be good, below .001. Polycarbonate is decent at
around .002.

Cheers,
Tom

But be sure to pay attention to UV susceptibility if your antenna is exposed to the sun. Many plastics deteriorate quickly in sunlight, and polypropylene is particularly bad. And of course you might need to consider mechanical properties. Polystyrene is brittle and breaks quite easily. Polyethylene and Teflon are soft, and Teflon cold flows. (I don't know about polyethylene but suspect it might also.) Polycarbonate is tough and nice stuff mechanically, but don't know about its UV resistance.

I can speak to polycarbonate in a very small way: PCB ophthalmic lenses
are treated to provide excellent UV protection.  But my understanding is
that pure PCB is not particularly UV resistant.  Without a coating
(which provides the UV protection) it scratches very easily, so in that
sense, it is a soft material.

Polycarbonate sheets in many sizes are found in do-it-yourself stores as window glass replacement. While expensive, most of those brands are marked "sunlight resistant."

Lowes, Home Depot, OSH all carry polycarbonate "window replacement" pieces here in southern California.

Those materials are apparently coated for UV protection. I put some
in the windows of a playhouse I built for my granddaughter and the
protective film was labeled as to which side should be out.

A private auction doesn't limit who can bid on the item, it just hides the
user ids of the people who are bidding on it. I bought an Icom PCR-100 from
him a while ago, and while I am quite happy with it I noticed he had a few
more for sale that where owned by the same guy with a 486 who was selling it
because he didn't know how to use it. However, there was an issue that came

up in the sale and he handled it very well.

```

Hello,
I think what we read on a spectrum analyzer is dBm for the specified range.

dBm/MHz is the PSD.

Lets say if the signal bandwidth is occupying 500Mhz (UWB) and has a PSD of -30dBm, then what is my power in the entire channel?

(-30dBm)*500 = (1microW)*500 = 500 microWatts = -3dBm

So do I see the -3dBm signal level on the spectrum analyzer in the whole bandwidth?

Please correct me if I am wrong.

Thanks.

A spectrum analyzer has filters with particular bandwidths. What you see displayed is the power passed by the filter. If you have the analyzer set for a 5kHz resolution bandwidth, what you see, then, is the power in (nominally) 5kHz of spectrum. To make things accurate, you need to understand the shape of the filter, as well. In addition, you can't necessarily use that number to find power spectral density in other than a gross sense unless you know that the power is distributed more or less evenly across that piece of spectrum. That is, if you use 5kHz resolution bandwidth and the signal has 99% of its power in a 1Hz segment within that 5kHz, the signal's actual power spectral density (at its center frequency) is much higher than the indicated power per 5kHz.

Many modern spectrum analyzers will display power spectral density directly for you, taking into account the filter shapes and such. Also, beware that resolution bandwidth and video bandwidth (on analyzers that have both) are not the same thing.

Cheers,
Tom

Hi folks,

I am responsible for the care and feeding of our GE pager transmitter on 150mhz vhf frequency range. I don't have the model number here as I am at home at the moment. It uses a single 4CX250 in the cavity final.

The problem is this, 10 watts output with 10 watts input, Plate voltage is 2100, plate current is very low at 100ma (normal is 270) and the screen voltage is around 60 to 80 volts.

The screen is supplied through an 80k resistor from the 2100 volt supply and has variable resistors to ground to set the actual screen operating point. I have placed as much as 500 volts on the screen circuit externally with the tube removed to check the bypass caps and they seem fine. They withstand the 500vdc without breaking down.
The tube is good, we tried it in another cavity (our spare amplifier).
The plate circuit is good also. At first I thought I had lost a plate choke or connection causing the screen to draw excess current.

I know the screen is drawing excess current causing the screen voltage to fall off. The control grid current looks normal and behaves normally with tuning controls. I don't get it?? How can I have excess screen current and yet have the low plate current?
The tank circuit seems normal, the tuning controls appear to work properly, in fact every once in a while the unit will work perfect for a minute or two making 250 watts output, then it goes back to acting weird again.

Anyone ever have a GE vhf amplifier do this?   Thanks!!

To add to what Tom wrote,

Ordinary spectrum analyzers sweep the filter across the band of interest, so what you see is not only the power in that filter bandwidth, but the power that's at each frequency at the moment the filter is there. Movement of the filter frequency constitutes modulation of the observed signal, which in itself creates sidebands. So what you see on a spectrum analyzer is heavily influenced by the relationship between the nature of the modulation causing the bandwidth spreading and the sweep rate of the analyzer. With some broadband signals, you can get vastly different displays by changing the resolution bandwidth and sweep rate, or with different filter shapes.

This is covered in detail in _Modern Spectrum Analyzer Theory and Applications_ by Morris Engelson (Artech House, 1984). I highly recommend it to anyone needing to measure and interpret complex waveforms on a spectrum analyzer.

Hi

Before you test perspex immerse the test piece in water for some days.
Maybe this simulates rainy days.

For very low noise frequencies, perhaps you could use a pseudo-random sequence generator made from fast logic clocked at say a hundred MHz, and calculate what the "noise" power spectral density in the output signal is. My only other suggestion is if you can make a 50 Ohm resistive terminator on the end a teflon cable that will go into an oven, then you can just measure the noise temperature directly... as long as you don't want an ENR over 3dB.

Chris

Does Engelson's idea of "modern" include digitizing spectrum analyzers, which
have already taken over most of the mid- to high-end of test equipment and --
as with digital scopes -- will most likely soon be in all but the lowest of
the low-end of instruments?

Thanks,
---Joel

Hi,

If you connect the 80k Screen resistor to ground via an ammeter, how much current do you see ? I would expect 26mA.

Are you sure that there arn't any shunt regulators on the screen supply ? Zeners, or an active regulator ? I have never heard of screen to HT without a shunt regulator before...

Regards,

Mark

I am going to buy a radio that I hope will last me many years. I want
to start with a mobile that will also serve as a base station.I am
looking at a YAESU FT-857D.

Any comments on the pros or cons of this as a beginner radio that can
stay with me as I develop my skills?

No, the book was written before those came about. I fudged a little by qualifying my posting with "conventional" spectrum analyzer to exclude newer technologies, but it sounds like "conventional" is rapidly advancing to become the newer types.

I got out of the SA development world just as digital techniques were beginning to develop -- my last patent (# 5,629,703), in fact, dealt with a way of reducing distortion in an A/D converter intended for use in a SA-like instrument. At that time, we were anticipating doing a conventional sweeping down-conversion, then digitizing it at a 25 MHz IF. Predictably, the digitization point has been moving toward the front of the instrument since then.

I haven't followed the technology since, but I'm sure the new ones use sampling techniques combined with an FFT, which is another way of imperfectly representing what the real spectrum is like. (Actually, you can never perfectly represent the spectrum of a real waveform, because any spectrum which is finite in frequency span has to have existed for an infinite time. Any modulated waveform is way outside this category.) Sampling produces its own, different, sorts of artifacts which are different from the ones produced by sweeping, although there are some similarities. You have to be at least as careful, and maybe more so, in interpreting a sampled waveform as one which is from a swept filter.

I'd be surprised if someone hasn't written an equivalent book to cover the new type instruments, although a lot of the material in Morris' books is still valid and teaches a lot about the nature of spectra. Morris was the driving force behind Tektronix's entry into the spectrum analyzer market, and the group's chief engineer and architect for a long time. He'd retired by the time I joined the group, and I only met him when he taught a couple of one-week courses based on his books. He's truly one of the experts in the field.

Roy Lewallen, W7EL

Thanks, that might be it, I'll check into it. I had the old DOS version, it worked ok but had a very strange copy protection scheme that made it hard to use.

Thanks,
Kerry, WD5ABC

I personally love my FT-857. Mine is the original model, not the "D" model, but I modified it for full transmit (I use it with transverters I build to get on other bands...right now I have transverters for 222 and 902) so it should work on the newer 60M band but I haven't tried it there.

It is a very small rig with pretty big features! When I ordered mine, they threw in the DSP board. I've never had a rig with DSP, but it sure does work nice!

I don't think you'd do much better for an all around rig (starter or advanced) for the money! Hopefully, others will chime in here as well.

You didn't mention what license class you have, but the rig would be great for any class. It has 100 Watts out on HF and 6M, 50W on 2M and 20W on 430. My only wish is that they would have built 222 in as well, but I built a really simple transverter for 222 (designed by W1GHZ... http://www.w1ghz.org)...I use mine at home, portable and mobile. No problems and I've had it for about 3 years now.

Happy hammin' !!!

I really like my FT-857, and would buy another to put in the other car if I had the cash to spare. Be sure to buy the separation kit and put the control panel where you can see it without having to divert your eyes from the road, and give *serious* thought to the fancy handmike with all the controls on it except Squelch.

The 857's big brother, the FT-857, makes a good shack rig, too, and the two radios use the same programming software, so that you can have the same memory settings on both.

The 857 has a nice, sensitive receiver, and I've worked Italy, Germany, Hong Kong and Taiwan mobile from central Oklahoma. It should really shine when the sunspot cycle gets a bit farther away from the minimum.

But it's not really homebrew.

Anyone got pointers to a good *and* inexpensive 2m FM foxhunting xmtr with integrated controller? Ramsey used to make just exactly what I want, and so (of course) they've discontinued it.

I'd like it to do a (programmable) CW ID, with a programmable delay from a minute or so up to 30 minutes, in roughly 1-minute steps. Xtal control is OK, but a good, stable VFO (DDS or DDS + PLL, rather than PLL alone) would be better. Settable power level would be good, too, and I can do with max power about 1 W.

Thanks and 73, de

In absence of dedicated controller, you could use one of the memory keyers,
AEA comes to mind. They have beacon mode, where you can program message and
set the repetition time.

73

>>
>> I'd like it to do a (programmable) CW ID, with a programmable delay from a minute or so up to 30 minutes, in roughly 1-minute steps. Xtal control is OK, but a good, stable VFO (DDS or DDS + PLL, rather than PLL alone) would be better. Settable power level would be good, too, and I can do with max power about 1 W.

Thanks, Yuri. If nothing else comes up, I may go to that, or roll my own.

I'm looking for something that doesn't involve using an HT. I'd lots rather use the HT on the fox hunt, and not risk having it stolen. Losing a transmitter/controller would chap me considerably, but losing my HT would be _bad_.

If I wind up doing the full-tilt-boogie 5-transmitter foxhunt, I'd really prefer not to buy 4 more HTs, for that matter. 5 ammo cans, each with a transmitter/controller and a battery inside and a BNC or SMA jack through the lid, would be a lot more affordable.

73, de

I would think you could get *used* HTs pretty cheap.

For that service, you don't need fancy scanning features etc. --
something like an old IC-2AT would do fine - and since you're going to
need to power the keyer anyway you don't really need a workable battery
with the HT.

I would think you could find something useful for less than the cost of
a new transmitter kit or the parts to build one.

>for a minute or two making 250 watts output, then it goes back to
>acting weird again.

I would say that the screen current is high because the plate voltage is swinging down too far (i.e. there is little or no loading on the tank circuit or it has become mis-tuned). One possibility, if it has one, is an open plate blocking capacitor.

BTW, the screen current on that series of tubes is often used as a tuning aid; some metering circuits even having a negative screen current position for when the grid gets too hot and emits electrons.

Cheers - Joe, G3LLV

You can use ferrit antenna rods. That works for receivers very fine in VLF band and for transmitters too - as long as the ferrit won't go into saturation.
That is a magnetic antenna and it is much shorter than the equivalent mentioned.

- Henry

Do a web search for the "Montreal Fox". I've built one that works OK.
The circuit board that's available is quite rough, but the thing is
buildable.

Ferrite rod antennas with perhaps -50 to -60 dB gain are useful since the extremely high band noise at VLF. It does not matter very much if both the wanted signal and the band noise is attenuated by 60 dB, as long as the wanted signal at the antenna terminals is stronger than the preamplifier thermal noise.

For transmitting, such antenna would be ridiculous.

In order to get 1 W EiRP as allowed on the 135 kHz amateur band in many countries, you would have to feed 1 MW into an antenna with -60

dB gain. The ferrite rod would saturate at much lower power levels
such as 1 W or a few mW. Most likely you might get a few nW radiated
power without saturating the rod.

> No, the book was written before those came about. I fudged a little by qualifying my posting with "conventional" spectrum analyzer to exclude newer technologies, but it sounds like "conventional" is rapidly advancing to become the newer types.
>
> I got out of the SA development world just as digital techniques were beginning to develop -- my last patent (# 5,629,703), in fact, dealt with a way of reducing distortion in an A/D converter intended for use in a SA-like instrument. At that time, we were anticipating doing a conventional sweeping down-conversion, then digitizing it at a 25 MHz IF. Predictably, the digitization point has been moving toward the front of the instrument since then.
>
> I haven't followed the technology since, but I'm sure the new ones use sampling techniques combined with an FFT, which is another way of imperfectly representing what the real spectrum is like. (Actually, you can never perfectly represent the spectrum of a real waveform, because any spectrum which is finite in frequency span has to have existed for an infinite time. Any modulated waveform is way outside this category.) Sampling produces its own, different, sorts of artifacts which are different from the ones produced by sweeping, although there are some similarities. You have to be at least as careful, and maybe more so, in interpreting a sampled waveform as one which is from a swept filter.
>
> I'd be surprised if someone hasn't written an equivalent book to cover the new type instruments, although a lot of the material in Morris' books is still valid and teaches a lot about the nature of spectra. Morris was the driving force behind Tektronix's entry into the spectrum analyzer market, and the group's chief engineer and architect for a long time. He'd retired by the time I joined the group, and I only met him when he taught a couple of one-week courses based on his books. He's truly one of the experts in the field.
>
> Roy Lewallen, W7EL

Indeed, we've been making spectral analysis equipment using FFT techniques since the early 80's or even a little longer. I believe the HP3577 from that era uses digital IF techniques, though I never got familiar with its "guts." Things have come a very long way since then. Just as Roy says, there's a whole different set of things to understand to get accurate, meaningful measurements out of them. Even knowing what I do, I still get surprised by the instrument's response to particular signals sometimes.

With respect to signals in finite bandwidths having to have existed forever, in theory that's true, but in practice, noise from sources beyond the signal of interest will always overwhelm those portions of the signal that are very far from its main power, for a huge proportion of practical signals. We'll keep pushing for higher spurious-free dynamic range and lower noise floors in the instruments, but it's probably fair to say they'll never be perfect, and signals are essentially always polluted by external noise sources as well, if only thermal noise in external resistances.

I believe you can find some information on the Agilent website about factors to consider when making FFT-based spectral measurements. I probably have a pdf or two hiding somewhere in my archives covering some of this, too.

Modern analyzers are backed up by some very impressive software that can help you analyze all sorts of things about modulation, signal variation with time, etc. It goes FAR beyond simple spectral displays of FFT results.

One of the key features of FFT-based spectral analysis is that you don't miss as much as a swept analyzer with narrow IF does. For example, if you have a signal that keys on for a millisecond out of every second or so at 100MHz, it might indeed be radiating a broad spectrum but there's observable energy only within a few kilohertz of 100MHz. An analyzer sweeping 50-150MHz with a 1kHz resolution bandwidth will take quite a while to do its sweep, several seconds, and may very well not be "looking at" 100Mhz, or close enough to it, at the time the pulsed signal comes up to be able to see it. But an FFT-based analyzer that's sampling fast enough to capture the whole 50-150MHz band at once can easily find the 100MHz signal every time it pulses on. The FFT is, quite literally, a large bank of parallel filters/energy detectors at evenly spaced frequencies. In combination with a "windowing" function, the effective shape of those filters can be adjusted.

Cheers,
Tom

Was Dennis Rosenauer around while you were still at Tek? Last I heard (a couple of years ago), he was working on their spectrum analyzers. As you're probably aware, Tek pretty much dumped spectrum analyzer development for awhile in the '90s, and something like 3-4 years ago hired Elaine May to be the new product group manager... she having been layed off when *Agilent* decided to dump *their* spectrum analyzer development! Sheesh. Rumor had it she was trying to get a a bunch of her former co-workers from Agilent to join her up at Tek.

These days Tek and Agilent seem to have realized that SAs are rather important, albeit with Agilent pursuing a more "traditional" architecture (very high frequencies, mix down to IF, digitize there) but Tektronix utilizing their high-speed ADCs from their scopes to just digitize directly and compute FFTs -- this approach limiting them to lower frequencies with noticeably less dynamic range, but giving them the advantage of being able to trigger on arbitrary masks withoug ever "missing" one.

Sure Paul. It is as a transmitting antenna for short-range only. Do you know
about:
http://www.ancom.no/
products? They claim their ferrite rod styled antenna works as good
transmitter. See their patent application.

regards -
Henry

...

Sheesh, indeed.  Where did you hear _that_?  Lots of shrinking happened
back then (and not just in Agilent, for sure), but it would certainly
be a stretch to say that they "dumped their spectrum analyzer
development."  That's a pretty gross misrepresentation of what went on.

Cheers,
Tom

I have an idea. This should thin the ranks of amateurs and let Big Brother have the bands as is desired. We all know the FCC wants to sell the bands to the highest bidder. In addition to the code requirement, lets have proficiency testing in SSB, FM, RTTY, PSK-31 and Packet. That should just about kill the code proponents off, as they are mostly too old, addled, and unable to learn. That way, even they won't be able to use *their* bands without these proficiencies.

Sounds like a plan, eh?

HTH

And just who do you think developed these modes? How new do you think these
modes are? It seems like everyone I contact on the "new" mode of PSK31 is
retired and has been for many years.

sample check Dee: how many people that you contact on ANY mode are not
retired and have been for years

went to our Radio meeting tues night and a talk was given on the "New"
mode PSK-31

if your sample is skewed towrd retirees as badly as mine........

I could go for that.

The more testing, the better. Then outsiders would look at the amateur
radio service and see valuable and capable operators, they would see our
spectrum wasn't being wasted by people that only know how to talk into a
microphone to communicate.

Thanks. :-) Great idea.

SC

Then make a couple CW contacts this weekend.

You'll get up from your rig afterwards and feel pretty good about being a
ham again.

Woha. A lot of info to assimilate. Thank you.

A few quick questions; the efficiency at higher frequencies does only
increse logarithmically, correct? Around where is the 'knee' where
increment of frequency no longer provideas a significant increase in
efficiency? - Ballpark numbers and guesstimates are perfectly OK for me,
since I'm only curious of the general idea.
Finally, what exactly do you mean by 'near field'? Is it an arbitrary line
in the sand that separates near fields from normal fields, or a completely
different physical phenomena?

Sort of, but not really. It's linear for electrically short antennas, but it's actually oscillatory in nature (albeit this occurs after you've hit a half wavelength -- not something you're likely to do at VLF).

> Finally, what exactly do you mean by 'near field'? Is it an arbitrary line in the sand that separates near fields from normal fields, or a completely different physical phenomena?

Any element that you're pumping energy into creates an electric and magnetic field. In a non-radiating component, that energy just "flows" around the element, e.g., the magnetic field diagrams you're probably familiar with for something like a solenoidal inductor. "Near" and "far" field aren't necessarily precisely defined terms, but the idea is that that energy that's just flowing around the element is in the "near field" whereas the energy that's actually radiating out towards Alpha Centauri is in the "far field." As a ballbark estimate, the near field of an element is within about a wavelength away (in distance) from it... hence the mention that, at 10kHz with a 30km wavelength, anywhere in your home is within the near field.

Mathematically, if you look at the equations for a dipole, the electric and magnetic field look something like E(r) or H(r) = foo/r+bar/r^2+bar/r^3+... (where r is the radial distance from the dipole), and hence the power in the field (the Poynting vector) is something like P(r) = baz/r^2+quux/r^3+... From this equation, you can see that over large distance the only term that matters is bar/r^2 -- this is the far field radiation. (Another way to define near field vs. far field, in fact, is to solve P(r) for r when the baz/r^2 terms equals quux/r^3+... -- reasonable enough, as at that point, the far field energy flux is equal to the near field energy flux.)

The above is a fair amount of hand-waving and probably some of it is just plain wrong :-) -- you really should pick up a book on the topic or start Googling. Krauss' books are excellent, by the way, in that the exercises are often "real world"-based, meant to demonstrate either how something really does work or, if it isn't practical, why not.

The Germans call near-field and far-field the Fresnel-region and the Fraunhofer-region, which is really a lot more colorful IMHO.

Not too long ago, I got an HP3400A (10 MHz bandwidth) on eBay for the purpose of measuring noise. Don't recall what I paid, but it was very reasonable. Since truly random noise also has low-frequency fluctuations, an RMS meter reading wanders quite a bit while measuring noise. I find it easier to eyeball interpolate an average reading with the analog meter of the HP3400A than with a digital meter.

Gary, WB9JPS wrote:

>I built a noise source as described by Bill Sabin, W0IYH in QST (1995) and EMRFD. Works fine, but now it's time for calibration. Chatting with Bill, he reinforces the notion that the best way to go is comparison with another calibrated source, or a direct measurement with a calibrated noise figure test set. NoiseCom used to provide this service to hams for <$50, but now they claim they have dropped that offer (it's about $600, now). So my question is, is there anyone in the SF Bay Area (I live in Livermore) who might be able to help? If someone owns a source or test set, perhaps we could get together. I'm open to other suggestions, too.
>
>FYI, this is primarily for testing HF rcvr performance. I'm building an R2-style DC rcvr, and it's turned into a nice research and education project, so I go a bit overboard sometimes, but it sure is fun. I'm also using an IQPro DDS VFO. I wrote a couple reports on its performance that are up on the AA0ZZ website.
>

Sorry I can't help with a calibrated noise source from this side of the Atlantic. The amateur microwave community hold regular meetings that always include a measurement session using calibrated professional test equipment. Given a calibrated professional noise source and a NF test set, it is very easy to transfer the ENR calibration to your HB source (especially if the room temperature happens to be 290K :-)

However, you don't really need a professional test set. You can make very accurate measurements of relative RMS noise power levels using a PC

sound card, and this opens the way to NF measurements. The only hardware accessories needed are a simple linear downconverter of the type described in EMRFD, and a noise source that can be gated by an output from the PC. For details and software, see:
http://uk.geocities.com/g8kbb@btinternet.com/newfile4.htm

The only other issue is that almost all professional noise sources are designed and calibrated mainly for UHF/microwave use. For your HF application, you'll typically be limited to just one transfer calibration point at 10MHz. You can rely on a professional source to have no nasty resonances between calibration points, but the ENR will probably roll off rapidly below 10MHz owing to the relatively low value of the DC blocking capacitor.

I was working on designing a surface mount PC board to build up a bunch of Bob Ball's nifty $25 PIC-based TNCs together so every RACES radio would have one built-in. . . and then read the source code and discovered it doesn't do AX.25 connected mode!

Any suggestions for a TNC that:

- Is cheap enough I can afford to give away 20 of them,
- Is small enough to install inside a mobile radio,
- Is AX.25 connected mode capable,
- Is NOT KISS or APRS (UI) specific,
- Is NOT dependant on ANY PC interaction or support,
- Will digipeat.

So far I can't find anything that meets all those requirements. We
are currently using a limited number of Alinco internal TNCs but they
are expensive, don't digi and only work with Alinco radios.

And - NO - I'm NOT looking for a different way to do what I need to
do: it's Plain Old AX.25 connected mode; NOTHING ELSE!

Thanks in advance,
Bill - WB1GOT

Bill -

The NO KISS specification I think eliminates the John Hansen products ?

He now lists these under the name Coastal ChipWorks - TNC X solution
http://www.tnc-x.com/

You can also ask John of his thoughts (his designs are also PIC based)
His TNC-X boards are expandable via an expansion header that allows the
addition of "daughter boards".

You can model the antenna system as a series connection of a loss resistance and the radiation resistance. The loss resistance will convert the RF power created with your expensive gear into heat :-), while the power "dissipated" by the radiation resistance will actually disappear as EM fields.

For full sized antennas, the loss resistance is small compared to the radiation resistance and most of the RF power generated will actually radiate. However, even with 1/4 wave vertical antennas, the ground losses can be significant, if not ground planes are used, but the antenna is grounded with grounding electrodes.

When the antenna size is below perhaps 1/10 wavelength, the radiation resistance drops by the square of frequency, so the radiation resistance can quite easily be well below 1 ohm at LF and below. The loss resistance (include grounding and loading coil losses) can be several ohms, thus the majority of the generator power is dissipated in the losses and only a very small part is actually radiated by the very small radiation resistance.

While the metallic conductor skin effect losses are proportional to the square_root_ of frequency, the ground losses are harder to predict, so the total efficiency at VLF frequencies is almost proportional to the square of frequency (not logarithmic). The 'knee' would be at 1/4 wavelength for a vertical antenna. At even higher frequencies, the radiation resistance would vary cyclically.

A bit expensive, but is this what you are looking for?

http://www.mfjenterprises.com/products.php?prodid=MFJ-1289W

It says it is for Windows and works with the 1278 (as well as some others)

direct way:
I read about something like:
phase = (I * diff Q + Q * diff I)/(I*I + Q*Q)
but I cannot remember it exactly.

Yes, the correct part!

But I cannot see a great benefit using your concept. What is better than others?

Everywhere I read about the necessity to remove AM. If the band is used for FM only, why then remove the not found AM in it?
I ran a simulation with Spice doing FM demodulator concepts comparision. The difference between limited and not limited FM product detector was not of significance. Doing the correct low-pass filtering after the detector was of much higher importance.

- Henry

A digital detector will have problems if the SNR is to low! If the SNR is
high enought, the all-digital system is just simpler to realize and consumes
lower power.

The limiting has nothing to do with receiving FM, it has everything to do
with getting rid of QRN.

Armstrong pursued FM because he wanted some system that was more noise
free than AM. Since FM does not have an amplitude componenet, that means
you can limit to clear out the QRN and some of the fading. The limiting
is what makes FM so appealling. Take out the limiter and the FM demodulator
will still work fine, but there'll be little point in switching to FM.

------------ REPLY FOLLOWS ------------

Here's what is working against you:

1. Frequency is too low for the power level you are using. At higher
frequencies in the shortwave region, 80 watts is plenty to talk around
the world, but not down in the audio range.

2. If you did have lots of power, you would still need an efficient
antenna. Unless you own an entire county, you won't have enough room
to put one up.

The US military does use very low frequencies in the audio range to
communicate with submarines world wide, but they have a pretty good
budget for it. :-)

It can be done, but not by you or me.

Bill, W6WRT

By "true" I mean a thermionic type such as an RF power meter (thermistor, bolometer, etc. sensor). Few voltmeters on the market have TRUE RMS measuring capability; those that do are specified as such and rather on the expensive side.
> >
> > . . .
>
> Not too long ago, I got an HP3400A (10 MHz bandwidth) on eBay for the purpose of measuring noise. Don't recall what I paid, but it was very reasonable. Since truly random noise also has low-frequency fluctuations, an RMS meter reading wanders quite a bit while measuring noise. I find it easier to eyeball interpolate an average reading with the analog meter of the HP3400A than with a digital meter.

I agree there on analog display versus digital.

Dug out my CD of old "saves" and found the Jim Williams article in the 11 May 2000 edition of EDN (www.ednmag.com). In that he lists the following as having zero error when compared to using the Linear true-RMS IC: HP 3400, 3403C, 3478; Fluke 8920A.

By the bye, the 1967-era HP pseudorandom noise generator has the following "calibration" procedure to check RMS output voltage: Connect it to an HP digital voltmeter-recorder, set it to slow speed and record 1023 voltage readings (corresponding to the slow-speed 'flat' pseudorandom waveform parts), then take the sum of the squares of all those readings and find the square root of it. Heh heh heh...I can just see a calibration technician doing all that work with a mechanical calculator in the 60s...with the QC chief storming in after an hour or so asking "You STILL working on that?!?"   :-)

> . . .

Neglecting ground effects, the radiation resistance of a four-sided loop 100 meters on a side at 100 kHz is 45 milliohms. The radiation resistance of a four-sided loop 10 meters on a side at 10 kHz is about 400 picoohms (4 X 10^-10 ohms). If you used 2 mm diameter wire to construct the loops, the first would have an efficiency of 0.7%, and the second of 0.00000016 percent. These are very optimistic, since they don't account for the considerable loss you'd incur by induction into the ground and objects for quite some distance around. They also don't account for losses in the required impedance matching network. And a receiving antenna would have the same efficiency.

You can easily get these numbers with the free EZNEC demo program from http://eznec.com. Or use a calculator and the simple equations you'll find in any antenna text.

The OP wondered if anybody had ever thought of this before. The answer

is yes, the first time probably well over a hundred years ago. Anyone
doing the simple calculations sees immediately why it's not a great idea.

Roy Lewallen, W7EL

OK Michael. So it is for fight against QRN and fading, not primary for being
immune to AM.
As my Spice simulations suggest; the FM demodulator works almost completely
comparable in analog (=not limiting) and digital (=limiting) mode.

What about the performance comparision of PLL demod and quadrature demod
concepts? Seems no much difference?

regards -
Henry

From a practical standpoint, I can't see much difference, unless OP has some
specific software beyond the typical terminal emulator.  The TNC-X works
quite nicely from a laptop and a mobile (haven't tried it with a hand held).
And consume little power.

However, they don't digipeat without the addition of a daughter card, and
that would drive the price up, maybe too high

WOW.

$50 today is like $10 when I was first licensed 30-something years ago.

$50 is just five more dollars than what the 2007 ARRL handbook
(paperback) is going to cost!

Tim.

Yes, I'm beginnig to see that now. :D However, I am learning a great deal in the process, and the equations I have found to explain the issue in detail don't seem simple at all. But if it was simple it wouldn't be interesting, now would it? ;)

Right now I'm looking at;
http://en.wikipedia.org/wiki/Near-field
http://en.wikipedia.org/wiki/Radiation_pattern
http://en.wikipedia.org/wiki/Fresnel_zone

Lucky for me I'm trying to build up an interest in math. Cos here's plenty of it...

Again, thank you all for your replies. It'll be a while until I really have an intuitive understanding of the subject like you all do, but I am patient. :)

That is an interesting perspective.

My first handbook, the 1971 edition, had a $4.50 cover price.  It
was preceeded, by about a month, "How To Become A Radio Amateur",
and I can't remember how much that was but obviously not much.

The latter book had a single tube transmitter built on a wooden
"chassis", though I can't remember if they suggested you scrounge
the parts.  I have no recollection of the receiver, but it would
have been a regen.

To get the numbers I came up with, all you need is the equation for the radiation resistance of a small loop and the resistance of copper wire. It shouldn't be hard to find the equation for the small loop, and it's very simple. At those frequencies, the resistance of the wire should be nearly the same as the DC resistance, so all you need is a copper wire table(*). Both should be readily available on the web.

Of course, if you want to know about other kinds of antennas and more detailed effects like the field intensity in the presence of ground, the equations can get difficult indeed, and some are too difficult to solve directly. That's what the modeling programs are for.

(*) At higher frequencies or with much larger diameter wires, you'll need to account for skin effect. This requires calculation of a square root and can be done on a pocket calculator as can the others.

Small magnetic loops with gains in -30 ..-60 dB range can be usable for receiving due to the extreme noise levels on LF and VLF, but for transmitting, they are far to lossy.

To get any significant communication distance, you would need a vertical polarised signal. The popular antenna among 135 kHz experimenters as well as in LF aeronautical beacons is a vertical tower with as much top capacitance as you can put up.

Look at the antenna systems of old ships using the LF band, these have multiple parallel wires erected between the masts in the bow and stern. These wires form the top capacitance and a vertical wire going directly from it isolator on the radio room to the top wires, which is the actual vertical radiator. The top loading will increase the current in the vertical conductor and hence vertical radiation.

Paul

The 7B71 is a single time base, which can be used as-is, or to provide a delayed trigger to a second time base plugged into another hole. When one timebase is used to delay another, it allows seeing an expanded-time closeup of a part of a waveform.

The 7B53A is a dual timebase -- two timebases in the same package. One can be used to delay the other, so you can do the whole thing with the one plugin.

I am having trouble matching to the input of a SA605 at 434 MHz.

If I apply a sig gen directly to pin 1 via a 1n cap I get around - 95Bm sensitivity. I then add my match and the sensitivity drops more than 10dB. I am expecting 10dB increase in sensitivity when input is matched correctly.

First I tried matching to 800R as per input impedance listed in the Philips APP note. I then noticed most applications matched to 1k5.

My current circuit is C-Tap (33pF to ground and series 5p6 to inductor).
18.5nH inductor (Q = 100) across input pins 1 and 2.
10n decoupling cap from pin 2 to ground.

Any help much appreciated.

Regards

David

A friend of mine has an ABE L60/TH, 60W p.s. UHF band (470 to 860 MHz)
amplifier, with a 3 cavity and a 6 cavity 500W tuneable filters also
supplied by ABE. All in mint condition. The part numbers are:

L60/TH/U/Ch 68 amplifier

L60/TH/U/Ch 68 STD I bandpass
L60/TH/U/Ch 68 STD I notch

The two filters are mounted on a 1U 19 inch rack mount, also mint.
He has asked me to sell them, any offers before they go on ebay?
Cheers,
Terry

You don't mention any adjustable components -- you _are_ tuning this thing, right? Your circuit will have a loaded Q of around 5, so you should see a pretty broad peak, but you will have to tune out all your stray capacitance.

Yes, but electronics follow a strange economy...some parts such as
batteries and pots haven't changed price much, but most are much
cheaper. You can now buy a`stereo FM receiver for $3.00 at Wal Mart.
In the sixties that would have cost at least $30.00. But today's
integrated radios have darn few parts that can be removed/reused.

Well, if it's any consolation, you will probably get lots more from the handbook--in terms of weight, at least.

Also, you don't say what the input caoacitance is. In my modeling, with an assumption of about 4pf for chip and strays, the voltage gain is about 9 (19db), the resonance is a little below 400 mhz and you'd be about 10 db down at 434 mhz. I agree with Tim...tune it.

Yes, I tune the series capacitance of the tap(3-10p trimmer), the 5.6pF is the calculated value.
The input capacitance of the IC is assumed to be around 2.6pF and I allowed a couple of pF stray circuit capacitance.

As the match is so broad due to low Q, I would assume the tuning is not critical and that any matching closer to the device input impedance would show a significant improvement in sensitivity.

Does anyone know what the impedance of the SA605 is at 434 MHz?

Philips APP note AN1994 shows a table that states 1785 Ohms // 2.5 pF at 250 MHz and dropping to 588 Ohms // 2.75pF at 500 MHz. If I interpolate the values between these points and assume the change is almost linear then I would expect the impedance to be around 800R // 2p5 or 2.6.

I do not have a network analyser to determine the impedance.

Thanks

Regards

David

Well, we agree that we should keep this requirement, but I don't agree
that CW should seen as reflecting poorly on us hams. CW operation,
albeit old fashion, remains a useful skill that I think should be
encouraged. I do acknowledge that the new digital modes and computer
based CW does make CW skills less necessary, but I don't think we
should consider it old fashion or out of date.

Your 10 nanofarad capacitor as a bypass on the low RF input is ridiculous.
It has to have a self-resonance down in the low MHz., if not the kHz.

Use a bypass something on the order of 50 pf if a leaded capacitor, and
something like 200 pf if a chip.

Jim

Jim,

I replaced the ridiculously large 10n with 200pF as suggested. Not a gnat's wisker difference in the response. Should this have some noticeable difference ?

The Philips app note AN1993 shows a 152 MHz RF receiver using even larger and more ridiculous 100nF values for the RF decoupling throughout the circuit. Why would the IC manufacturer use these values ?

Regards

David

What are some RF modules that work well to transmit serial data from a computer to another device.
Will consider homebrew circuits.

Thanks

SW

Only if the low side RF input grounding makes a bit of difference in the performance. It seems as though this device is rather numb to doing anything with the other balanced input.

Several reasons come to mind. The aforementioned numb unused input. They found some interesting motorboating (low frequency) proclivities and started throwing capacitors at it until they found the right value. The applications engineer was two weeks out of school on his first real RF circuit.

Jim

Many tnx to all- I did look up the patent. I really appreciate your efforts.
I ordered a 7B53A and will see if that is adequate. Jim.

Tony,

If I'm in a hurry, I order SMD's from Farnell.

For "planned" homebrews, I order SMD combo packs from Chinese E-Bay traders. You can find 5000 assorted and bagged resistors and 3000 ditto capacitors for less than £10 incl p&p. Look for "SMD resistors" on e-bay.

I even buy more expensive SMD'parts on E-bay and you can find real SMD bargains. Many SMD components have a "best before" date with less than a year solder warranty from the suppliers. It basically means that they doesn't guarantee the components if machine soldered. As an example, I bought 100 pcs of 33.333MHz SMD oscillators for 99 pence plus £2 p&p. That's less than 1 pence per oscillator! (plus p&p)

Guess why a lot of my designs currently are based around 33.333 MHz Epson oscillators...

Buying SMD oscillators on lower freqs are normally around £3 to £7 each.

Cheers

Dan / M0DFI

ROTFLMAO - I had to share this

I took a peek on Bay and the first interesting I ran across was from a
British supplier (I'm in the U.S.) There was a link that stated that the
translation was provided by eBay and might not be accurate. So I clicked on
the link and read it in the original English! I'm not so sure what they
translated since the word colour never appeared.

David,

What type of inductor are you using ? SMT can be sensitive with proximity issues.

Are you 100% sure that capacitor values are as you hoped - SMT can be a pain to verify.

Note, I did drop the 33pF to 15pF to improve return loss.

The 6.5pF cap is the most sensitive of all parts in the cct.

Any chance of a photo of the input network and signal coupling ?

My current bet is an inadvertently loaded wrong value component. Been there, done that etc.

Regards,

Mark

Not entirely true. Linux doesn't always have the hardware support,
especially on newer boxes.

> You can also install Linux
> on top of windows (on the same computer anyway) and dual boot, so you
> can have your cake and eat it too (or have your poison and antidote too
> in my opinion!).

And why would you? Why would you suffer the complexity and frustration of Linux if Windoze is working just fine for you?

Personally, I fully enjoy having Linux servers an Windoze desktops on my home LAN, and with the magic of Cygwin, I can have Linux tools on my Windoze box, and seamless access to my Linux apps, withough fully suffering the clumsy Linux desktop.

But that is just me. Most folks want to use the applications, not the OS. Most hams aren't going to write programs, and the features of Linux will be lost on them, but the complexity sure won't. For them, all they want is a little Digipan and email, why on earth would they subject themselves to yet another set of stuff to learn? As far as i can tell, the only ham app on Linux that is better than what is available on Windoze is gEDA. Everything else is harder to use and less capable.

Now, I have a lot of ham apps on Linux that I have personally written. These provide me with functions that aren't easily available on Windoze, and the Linux environment makes it much easier. But I'm not most people. Not too many hams are comfortable writing their own applications, or even if they could, that isn't how they enjoy the hobby. For most people, including most hams, Windoze serves the purpose.

Everyone has their own set of needs, and one size doesn't fit all. I suspect there may even be some people for whom the Mac is the best answer, although I can't imagine who they might be. But the getting in price for Linux is still pretty high in terms of learning curve, and for most hams, the return is close to zero. So why bother?

You indicated you had no problem with the circuit. Programming a PIC is more like designing digital logic than it is like programming in BASIC. It may be a little weird, but it isn't the least little bit hard. Its mainly a question of getting over the fear. And as Allison pointed, out, a parallel port programmer is pretty simple. In fact, it's a pretty lame junk box that doesn't already have the stuff. OK, maybe you need to buy the DB25 and the IC socket, but the rest is just any old transistor, and a few resistors and diodes.

> why would one give *BOTH* AC and DC? Bad diode(s)?

There are four types I have come across:

1: transformer only for AC
2: transformer and diode bridge for DC
3: transformer, diode bridge and linear regulator
4: switching regulator

The voltage output and the current output of the first two type depend upon the load. So for a type 2, for example, if the nameplate says 6 volts and 500 mA. That's exactly what it means. With a laod of 500 mA, the DC voltage will be 6 volts. a lighter load will result in a higher voltage, and a higher load will result in a lower voltage.

The last two will provide you with a fixed voltage for which they are rated. So, for 6 volts and 500 mA, the voltage will always be close to 6 volts as long as the current does not exceed 500 mA. Switchers may require a minimum current draw of about 10% of their maximum current rating. Thus one rated ate 500 mA needs a minmum load of 50 mA to provide the rated voltage output.

I have disassembled wall warts and used their guts for power supplies in projects. It works quite well. As our town's recycling center is full of old electronics, I have assemble quite a nice selection of wall warts that I use as PSs in projects. And the price is right, zero, except for your time.

Al

Excellent response. I too have a Linux system on my shack computer
dual-booting with Winders. I removed Linux from my main computer as
after several months of searching I could never find a decent driver
for my video card and wasn't about to buy another card when there was
nothing wrong with one I have except there aren't any Linux drivers
for it.

Plus setting the sucker up is a PITA. Kind of a cross between DOS and
Window '98. Finding extensions, plugins, or what ever you may call
them is some what like a scavenger hunt and takes a LOT of time and
effort.

If one takes the time and endures the learning curve the results are
often quite good. The system is very stable and works well.

73,
Danny, K6MHE

Linux- not just for geeks anymore. Mepis distro, even computer illiterates
can use it.

"This is your office app for letters and spreadsheets, this is
your web/file browser, this is your e-mail. Need anything else?"

"No, that looks easy enough."

You can even make it look and feel like "Windows" if they are hesitant to
use something that seems unfamiliar.

```

I had been on ebray since they billed via postal mail and gave $10.00 credit
to start

you out.

Recently I had the wonderful experience of having paid my ebay via Payless
Pal and when

I went to pay the small bill.. a few bucks.   THEY made an 8 cent error in
the

bill transfer and so I figured they would just bill it on the next months
cycle.

BUT! What they did was to debit a closed bank account.

I had opened a checking account to get a Payless Pal account and closed

it so my real money was never in jeopardy. So what the idiots had done then
was

to bill me an additional $15.00 for a bounced debit they should have never
made.

In the mean time ebray has gotten so big I could not get any 'Real response
from a

Real person'   Like dealing with the government! I could find no Phone
number to

call and explain THEIR ERROR.

I just kept getting junk Spam replies from ebray.

It makes them feel good telling me I can not use ebray.   pftpftpft!

So I have since closed my ebray account.

AND my Payless Pal account a soon as I heard ebray had bought them.

For several months ebray kept billing me with additional "late charges"

HA HA ebray and Payless Pal get stuffed!

All over 8 cents they have lost a lot more than that in business since I am also

disabled and did shop over 100 items on ebray. It WAS convenient to use

and not walk through so many flea markets and hamfests. My rating WAS over 98%

Couldn't please everyone, and some sent me junk from trash cans smell and all . lol

Thanks for the vent.. off my soap box now and shopping elsewheres. :-p

So you closed a bank account and didn't tell PayPal?   This whole mess is
your fault.

eBay is the best.   I've bought hundreds of items worth many thousands of
dollars.   Most of it could never be found locally for the same price.
Anytime I'm looking to buy *anything*, I look at eBay first.

Mike

Those of us that have gone through the trouble of getting there know
the rewards of Linux. I agree, it's not something for everyone, but I
would think that if you have the brains to get a ham ticket and build
your own gear, you can figure it out. Also Ubuntu, Linspire (and

Freespire) provide a brainless install that usually just works.

As for hardware support, it's much better than it used to be. Almost every sound card chipset found on today's motherboards are supported. Nvidia and Ati both have Linux drivers for their latest video cards (though they are binary drivers and must be downloaded and installed by the end user....complete instructions on the manufacturer's wwebsites). Intel's own graphics chips are supported directly by the kernel.

About the only thing I find lacking is Macromedia Flash support for Linux, though there is a GNU project to provide it (gnash).

Al (no.spam@wanted.com) writes:

> I have disassembled wall warts and used their guts for power supplies in projects. It works quite well. As our town's recycling center is full of old electronics, I have assemble quite a nice selection of wall warts that I use as PSs in projects. And the price is right, zero, except for your time.
>

The ones I've opened up (mostly to see if the problem was fixable) have never seemed too adaptable. The the transformers are too integrated to the plug, or at the very least have no means of mounting them.

I admit that they are useful for projects unopened.

But I find consumer electronics (VCRs, radios, whatever) are often a better source of small transformers. They at least come with mounting holes. Of course, a fair number of VCRs I've opened up recently are using switching supplies.

I tend to bring home switching supplies from computers I see lying on the sidewalk waiting for the garbage truck to pick them up. But ironically, I take out the switching supply board, and build analog supplies inside, using parts I've salvaged from other equipment. Rare is the time I actually need the current of a switching supply, or the noise, yet the cases make quite nice boxes for analog supplies. I leave the AC socket in place, and then just use one of those cords that plug in, they now being in plentiful supply from other junk I've collected.

They'd even make nice construction boxes, covering the back panel with a piece of metal or circuit board.

On the other hand, when I got an older Powerbook some years back, once I'd scraped up the details for the missing AC adaptor, I pulled the switching supply out of an inkjet printer and it was the 24 volt supply I needed, and I had the needed AC adaptor.

Given that this is about a contest about building a radio, in a newsgroup
devoted to the building of radios, I would expect a higher level of interest
in Linux.

But that said, at this point one could even distribute any needed software
along with an existing distribution.  Put it on a Live distribution,
and people treat the whole thing like an application.

Uhh,why a Transformer,of course..
The ones with the DC output will have a rectifier diode or two (or maybe
even a FWB,if you're lucky) and usually a filter cap,but not always,IME.

The AC ones are usually just the transformer,and that's it.

Some "wall warts" I've come across were actually really tiny SMPS's,you
can usually identify these fairly easily,they're really light compared
to the "iron core transformer" type.. These may be regulated,the
iron-core types above almost never are.

AC and DC output?
Are you sure you're not measuring the ripple? They usually have very
poor filtering,plus after time the cap(s) dry out,and make it even worse.
Or,it could be the diode(s),they've been known to fail aswell.

Nope... closed account ebray opened with that was used long ago.
Was active via Payless Pal till they made a mess of it all so I closed that account
so they couldn't rob me just for THEIR 8 cents MISTAKE.   Plus their withdraw
penalty, plus their late fees.   UGH!
Had they replied with an 8 cent request there was more than 8 cents in
my Payless pal account at the time.   Just as reasonable as the Gvnmt LOL

Just the same as auto deposit from anyplace... they have access to get what
ever they want and you have to litigate it to get your own money back.
Being on SS disab' I'd starve before I got my money back if any were taken.
I never trust them with my whole paycheck.... I wonder why anyone does.
Oh!.... That's so they can get in the news by being e-robbed. Phished etc.

Good luck Y'all

I also keep my Norton AV etc up to date and turned on ALLWAYS

Well, its "rating" is "9VDC 200MA",
but my Simpson 260 VOM gives it's output as 15V DC AND 15V AC.

I've NOT looked at the output with a 'scope (yet).

To all radio enthusiasts and members of the group,
Hey guys and gals, you are all invited to join the "radio_programming"
group in yahoo groups. To subscribe, just sent an email to:
radio_programming-owner@yahoogroups.com

I'm the group moderator and as a reward, I'm giving away some freebies
here :)
http://groups.yahoo.com/group/radio_programming/files/
If what you are looking for is not in the list, don't hesitate to drop
us an email. We might be able to point you in the right direction to
get the latest software or programming utilities.

Also we have RADIOS FOR SALE ! We got radios from Kenwood (TK models),
Icom (IC models) and Motorola (HT & XTS APCO-25 models)
Contact us at radio.programming.owner@gmail.com for all your
programming needs and radio equipments!
Thank you for your time..

I really don't want to debate this but will add this comment: I did
not find that true with Ubuntu. Try playing videos or mp3s without
addding a bunch of stuff after the install. Its not a slam-dunk yet.

It really a choice thing and we don't all make the same choices. <G>

very 73,
Danny, K6MHE

Hi,

My 940 was working good for while, but now the S-Meter lights and the VFO display have started to flicker. They flicker at random times very quickly (all at once). The LCD display bulbs don't flicker, but they have both burnt out now. And I just replaced them less than 2 years ago (with Kenwood factory replacements).

I checked the voltage to the power amp and it reads 28.6 volts. The S-Meter (lights) read 13.6 volts and when the flicker occurs the voltage very quickly varies from ~6 to 13 volts - never above 13.6 volts. Is this some kind of voltage regulation issue? I can't get it to do this by moving wires around and pushing on things. It does only seem to effect the lights the are controlled by the dimmer switch.

On a side note, I've been reading several posts about the 2N5885 that regulate the 28v supply for the power amp failing and wiping out the MRF-485 transistors that are no longer available. Does it make sense to preemptivly change the 2N5885 transistors to help prevent damage to those MRF-485? I use my 940 daily - and its on most of the day.

-Scott,WU2X

Scott,

May I suggest the TS-940 web page? Jeff King ZL4AI / DU7 (N5IW also has one)
One stop shopping for almost every issue, mod or change noted for the TS-940
The web page is so big -- it is in 2 parts!
http://homepages.ihug.co.nz/~jaking/TS-940_02.htm
http://www.jking.kol.co.nz/TS-940_02_part2.htm#_Toc146779962

The power supply, as you have noted, has been an issue for other operators.
http://www.jking.kol.co.nz/TS-940_02_part2.htm#_Toc146779932

Kenwood TS-940s AVR board, by N0XWR on February 28, 2006

You won't find an AVR board for sale new -- you should endeavor to fix the one you have.

First, check regulator Q103. it is in the rear left corner of the rig as the rig faces you. it is on the heatsink for the power supply. there are three regulators side by side. it is the one on the far left. no matter whether you replace it or it is good, it is imperative that you cut the connector off of the three wire harness that plugs on to regulator Q103 and solder directly to it. this harness comes from plug-in #2 on the AVR.

Over time the connector overheats and fails and cannot carry the 20-30 volts to and from that regulator. I have seen the problem many, many times. when the connection to that regulator fails, it takes out Q6 on the AVR board, so check it next.

Clif at AAvid Electronics, (now back in repair business at http://www.avvid.com) helped me get through the problem. also check D3, D9 and D14 which are zener diodes on the AVR board. they can be checked right on the board with a multimeter. the board can be removed easily. as you unplug the wiring harness use a sharpie and number each connector so that you can reinstall it easily. make a diagram, too. use small long nose forceps to unplug the connectors to the AVR board.

Incidentally, Q103 is part # NTE377 available at Mouser. Q6 is part # NTE382 also available at Mouser.

I have the part numbers for the zeners if you need them.

73s Jerry N0XWR

Not true. A fairer statement would probably be something like "there are significantly more free development tools for Linux than there are for Windows." On Windows, the "express" editions of the Microsoft compilers are free, older Borland tools are free, GCC is free, etc. On Linux, there are plenty of commercial development suite, which in many cases are well worth the money.

> and Linux
> will run on any computer that runs windows.

Also not true. Especially with laptops, drivers for Linux are often non-existent. In fact, where I start thinking, "hmm... I should do something with Linux..." the *first* thing I have to consider is whether or not I have a PC around that'll have its hardware fully supported.

I'm not that aware of how many (and how good) developement tools are there
for Linux but...see bellow...

My little story....

I have been told that there are laptops out there, with Windows
pre-installed, that will not even run DOS or Win3.1 any more.

Laptop support for anything other than what software the laptop was
designed for is a major problem.

I have had vastly more success intalling the earlier versions of Linux on
"any" PC laying around. Just like Windoze, Linux has also tightened up its
hardware compatibility requirements and particularly in the driver
category.

I've had, and installed, from Red Hat 4.2 to 5.2, 6.2, 7.3 (problems with
7.4, very buggy GUIs in 7.1,7.2), and mostly failure with one of the
Workstation (Taroon, version 3.0) versions (based on the 3.5 inch
boot disk with included CD-ROM driver portfolio was changed from a small
number of prior CD-ROM drivers to new RAIDs, etc, and the new drivers
don't recognize anything older than about 4-5 years, now). And, I was
profoundly disappointed. Also, that same Linux (Taroon) required 256 MB of
ram to run. It would boot with less (32 mb), but barely get the GUI up.
Anything beyond that would run into the swap partition and be slow as
hell. Actually both 6.2 and 7.3 (which installed sucessfully less often
than 6.2 or 5.2) are pretty good (eg. drag and drop file manager, gFTP,
automount-dismount drives, etc). StarOffice 5.1 & 5.2 installed well on
5.2 and 6.2. The problems with 7.3 and prior were the buggy web browsers
or they would crash on moderate to advanced websites.

I never set up the firewalls, IP chains, or whatever, and some months
after I was running it on the intenet, I got hacked (I actually witnessed

it as it was happening: hard drive started cranking like mad, and lots of bytes were being downloaded (as could be seen on the download bytes/sec rate meter and graph). By the time I could get to the phone line to disconnect, the bugger downloaded a rootkit somewhere and every time I booted it up, I could see a package of outgoing data (red bars) leave my box (and without confirming green bars) to some unknown point on the internet. At a later point, I nuked the HD and re-installed.

As an aside, I still run DOS & Win3.1 for a lot of internet aps. At one time, www.securityspace.com ran free vulnerability tests with hack attacks (I think www.grc.com does too) and could not hack my Win3.1 with Netscape 2.01 dialer (probably because it has no ports for anything but email, ng, ftp, and http protocols), but it could hack my Linux and Win98SE boxes (without ZoneAlarm). Most of the time I access my shell account with a DOS terminal program (dialup terminal mode, not ppp). I think my home box is pretty safe that way (not much is going to cross from Unix to DOS, and I don't keep any vital info in files/folders on my shell directory.

Flash working fine here on Mepis 3.4-3.

Even runs my LinkSys WPC54G wireless card when other distros wouldn't.

Wow... someone probably just reefed on a video cable that was still screwed
into the connector and ripped it off?

I would wager that you'll find it will work just fine if you can successfully
re-attach a connector (and repair any damaged traces!)

===================================
Question : Do you run 'Simply Mepis' from a live CD or have you
installed that distro on your HD ?

'Simply Mepis' upgrades come hard and fast ; last month the Linux Format
magazine's  DVD carried version 6.0

They shouldn't be coming "hard and fast" from here on out. Mepis is now
Debian-based and will follow that distro's roll-out schedule(s). There
can be/will be security updates -- which I believe is A Real Good Thing.
The updates are done with ease.

But new, full releases will appear less often. 'Tis said, as well, that
Mepis release's will each now come with "Long Term Support". Dunno what
that means in actuality, but I've gotten damn tired of Mandrake
deprecating my installations each time I finally get them fully fleshed
out, fine tuned, and stable. Then it is upheaval all over again.

I will be moving off the Mandrake ("Mandriva" - yeech!) distro (MDK 10.2
on my primary box), and I have recently installed Mepis 6.0 on my
'down-level' box (was MDK 9.1). Mepis 6.0 installed as slick as you'd
ever want an install to go.

Recommended.

There are TWO different flash plugins.  Macromedia is NOT supported
under linux.  There is another pluging also called flash that is.

Ubuntu tries to be a totally free (as in freedom) distro so they don't
distribute closed source drivers and plugins by default. As you noticed
it's possible but requires user intervention. There are scripts
available to do this for your with one click.

I originally ran it from a Live CD to test it. It found and set up all of
my hardware without any messing about or configuring on my part. After a
few days I wiped out Mandrake and installed it to the HD.

The only thing I really miss is Midnite Commander...and a partition that
```

got munged when I disregarded previous experience and was bopping back and forth between Partition Magic and QTParted. I could re-write the partion table by hand with a hex editor but it's tedious work and I'm not sure that what's gone is worth the effort.

This machine is set up to dual-boot with Win 98, but the only reason I keep it is for one business app that manages my inventory and invoicing. I'm used to the way it works and too lazy to port it over or try to convert it to something else.

I have the Mepis 6.0 Live distro but this is working fine. It ain't broke, so I'm not going to "fix" it. But if I decide to build a new laptop with one of those nice 17" screens and a dual-core AMD CPU, that is most likely what will go on it.

I and other readers of rec.radio.amateur.antenna would really appreciate
it if you'd leave that newsgroup off the lengthy list you post this sort
of thing to.

If you're not willing to do that, perhaps some of the people who feel
compelled to respond would be thoughtful enough to remove that newsgroup
from the list receiving the responses.

Well, this doesn't seem very relevant for folks here in
rec.radio.amateur.boatanchors.  We think the requirements
should include being able to bench press a Collins R-390
and being tested on changing coupling capacitors with the
B+ live.

Other folks may consider other tests, for example testing
someone for the ability to hold down the key for ten minutes
straight while shouting "This is my channel, you don't own
this frequency" over and over again.  This is a skill that
is becoming increasingly popular.

...

> Such units actually have a bridge rectifier across the AC mains and supply DC to a switching regulator running at 20-50khz. There is an isolation transformer running at this frequency (it's core is just a small bit of lightweight ferrite). The output of the isolation transformer feeds another bridge rectifier and filter (at ~40khz not much of a filter is needed, small caps and chokes!). There may then be a linear or switching regulator. If the later, it may actually regulate by changing the switching frequency/duty cycle of the original switcher at the AC mains input. In this case the feedback is by means of an opto-isolator for safety.

In small ones (not a whole lot of power; things like 5V at 1A like I have in front of me), the switcher is commonly a flyback type, and the regulation is provided by monitoring how far the primary flies back. The secondary side is a single rectifier diode feeding a filter cap. Knowing the turns ratio and the expected losses in parts like the secondary rectifier, you can achieve pretty decent regulation that way. They commonly run at much higher than 50kHz these days. There are some small ICs that make the job very easy. One characteristic of the switchers is that they commonly run on 100-240V, 50-60Hz input, though not always. It's rarely the case that a mains-frequency transformer model will operate properly over such a wide voltage range. Wide input range switchers do make travel to countries with different mains voltages more convenient.

Cheers,
Tom

The Macromedia flash plugin works fine on my Linux box. You can get it
from:
http://fpdownload.macromedia.com/get/flashplayer/current/
install_flash_player_7_linux.tar.gz

or with this shorter URL: http://tinyurl.com/prmdd

I think it is closed-source, binary only, so it will probably only
work with X86 versions of Linux.

Note that Macromedia are called Adobe these days.

Anyway, thats enough OT for me. This is turning into a
Linux advocacy group :-)

73, Ed. EI9GQ.

Hi all,

a good friend of mine in IT9 (Sicily) has a very nice General Microwave
Bolometer model 476. By mistake he applied too much power and ...
voila' ... the "476 head" failed.
He has now at least 8dB error. He would like to repair replacing the
TFT element that now has 180 value versus the expected 150 ohm.

The Head is model 42040A ok for up to 20GHz.

Thanks for your help

==================================
For the purpose of this reply I deleted a number of NGs since I only
subscribe to rec.radio.amateur.homebrew

The problem with Usenet is that you can post any messages to multiple
NGs with the consequence that the messages appear in non-related NGs
If this were NOT possible , NG-life would be so much more
effective/efficient and .... peaceful.

I know that this is off-topic, but since there are many homebrewer/designers on this group, I will mention it. I am parting out an HP 8557A. This is the one with the LED display.
I purchased it from a local hamfest and discovered that the sweep board had a problem. All of the other boards, including the front panel assembly with the attenuator should be ok.
Let me know if you are looking for any of the board/assemblies and we can work out a reasonable price.

Pete

Various digital modes do better under low SNR conditions than CW, but they do require a computer at both ends to perform the encoding and decoding -- some people don't like that fact, that you seemingly need "more equipment" to work such modes than you do with CW. It's a bit of a red herring, however, in that these days pretty much every single amateur radio being sold commercially has a processor (computer) in it anyway, and while some are strictly for "control" (not modulation/demodulation), the percentage that does have raw number crunching power increases every day, and within a decade it's a fair bet that over 90% of all commerical amateur radios will use DSP techniques for modulation and demodulation. (Cell phone went to DSPs somewhere between 5-10 years ago now...)

> Does no one run "flea power" anymore?

Absolutely they do, and it's a really cool part of the hobby... but for every

100 amateurs, I would guess that the number running QRP on a regular basis is about 1.

Hejsan, "Lethall Harry!" :-)

Excellent new pages on your website. The two on homemade
tuning capacitors is very good. Keep it up, please, should be of
help to many hobbyists, not just licensed radio amateurs.

My sole experience with QRP was accidental. I had reduced power to 5 watts
to tune to a different band (17 meters) and forgot to turn the power back
up. As a result I found myself speaking to a Swiss ham form my southern
Oklahoma shack with 5 watts and getting a reasonably good signal report. I
realize that for real QRPers 5 watts is high power, but for me it was an
unusual pleasure. Moreso because bad weather had me using an indoor dipole
mounted on the wifes sewing room ceiling (about nine feet above the earth).

Man, do anything you can to stick around.  It's going to be good, and 10M
FM is just more fun than anything.  Get a PRC-8 and take lots of vitamin C.
I predict that this next peak is going to be a really good one, at least as
good as '78 was.

I did, but all of the unit is up for grabs. It is a nice 60dB attenuator. I've got all of the board in a box..........probably, I will end up taking it to a hamfest if I don't sell the parts sooner. The LED readout board seems to be the same as on my 8558, so maybe I will hang on to that.

Pete

Signal to noise ratio would be important, to be sure, however with the proper application of some limited computing power I'm sure one could construct a detector that would work with seriously low SNR. It is amazing what DSP's can do now days..

> 2. No distortion on the signal such as occurs from aurora, meteor scatter, etc.

Again, I've seen spectral displays that clearly show CW transmissions that could *not* be heard.

> 3. The code sent is nearly equal in quality to that sent by a computer. Some one using paddles may achieve that but if they are sending with a manual key or bug, that is highly unlikely.

Sending code is not in question. Surely a computer is able to open and close the keying faster than a transmitter can possibly transmit. Also, remember that the faster you key, the higher bandwidth your signal will require and the higher the SNR will theoretically need to be for it to be decoded at the receiving end.

> I have frequently been able to copy better than the computer and my code skills are quite modest. The only time it beats me is when the code meets the above three criteria and is too fast for me to copy.

I would contend that the software you are using is not utilizing the inputted signal at it's full potential. I've seen audio processing techniques that could pull out inaudible signals that where more complicated than CW would be.

I would also ask if you where copying random characters or where you able to "fill in the gaps" by using the context? The latter would be a very different problem for a computer to solve.

> > I'll be willing to bet that there won't be much improvement over CW in the raw "get the message though under bad conditions" power with the new digital modes using the same bandwidth as CW. Simple is under-rated in my book.
> >
>
> I'm not sure I understand what you are saying here. Did you leave something out?
>

I'm saying that if you pick any digital mode, restrict the bandwidth to that of the CW signal with the same data rate, keep the SNR the same with the same error rates, CW will be about as good as you can get. Not bad for an operating mode that has been around as long as CW.

I bought one of these some years back. I made the same search you did and came up empty-handed. I've been happy with Baudot and VHF packet so never really got too serious about the other modes.

I did hook up the accessory audio I/O on my rig to the soundcard in the computer, with the intent of making unattended recordings (for AM BCB DXing - works great!) and using the computer as a voice keyer. Turns out the same connections are appropriate for PSK31 and other soundcard modes. Very simple (one transistor, one resistor) serial port interfaces are possible to let the computer PTT the radio, or you can even buy one preassembled, and if you don't have a soundcard they're pretty cheap.

I still use the 1278 for Baudot.

Define "common operating conditions".

For a contester, common operating conditions often include murderous QRM.
Yet contesting is common. I've always maintained that one can construct
various scenarios such that there is one where the particular mode under
discussion is "the best".

For ragchewers, common operating conditions often include manually sent CW.

Yes and there are some very fine software programs already available. But
even so they fail before the "EAR" fails, assuming a trained and experienced
operator.

>> 2. No distortion on the signal such as occurs from aurora, meteor
>> scatter,

>> etc.
>
> Again, I've seen spectral displays that clearly show CW transmissions

>

So I've seen displays of many types of signals that cannot be heard. That
is an entirely different issue from distortion. When the auroras start
playing, PSK (as an example) is so distorted that no matter how strong the
signal, the computer cannot decipher it. If a CW signal is distorted but
loud enough to hear, the human ear/brain combo can still decipher.

Receiving is the issue. If the received code was manually sent, the
computer often fails.

I''ve tested everyone I could find. I'm one of those people who gets
pleasure out of trying all the new gadgets & software I can find and afford.
I've also seen inaudible signals pulled out of all kinds. That's quite
feasible when the bands are in good shape. Add a little thunderstorm
activity, geomagnetic disturbances, solar flares, etc and the machine can't
decipher them. It's not a matter of signal strength but a matter of signal
quality.

> I would also ask if you where copying random characters or where you

Yes it is a different matter. Humans definitely have the edge on "fill in
the gaps".

>

Ok, I understand. Actually many digital modes are, by their nature, narrower than CW already. You would have to open up the filter to get to the same bandwidth. Again the key item is quality of signal. For example, aurora induces phase shifts on PSK (phase shift keying) and makes it undecipherable. It also induces phase shifts in voice and CW. It gives the voice & CW signals a buzzy, raspy sound. Yet you can often understand voice when PSK is undecipherable.   CW, when there is a phase shift, sounds like a series of buzzes but can still be copied if you are used to it.

And yes CW does a fine job and will continue to be advantageous under certain conditions.

Hello All,
I was going through an ADC tutorial and realized that they use the term input bandwidth more frequently as one of the important factors to be considered before choosing an ADC.

Based on my search, I found out that "the input bandwidth is something that determines the maximum bandwidth of an input signal that can be accurately sampled, regardless of the stated sample rate".

http://www.diamondsystems.com/slideshow.php3?name=ADBoardTutorial&page=4

I am not sure why is this input bandwidth different from Fs/2. From the above link, one of the example has Fs/4. Is it just because to increase more precision that we use a sampling frequency 4 times the bandwidth of the signal?

I assume for practical reasons, we oversample it but that is for more

precision (correct me) but the Nyquist criteria still holds good for
sampling the frequencies upto Fs/2. That means I can still get the
original signal. I am not sure about the accuracy though.

Also, can I say that if an ADC is oversampled 4 times the Nyquist rate
(Fs = 4*BW), then is my input frequency given by Fs/4? Assume single
channel case.
Correct me if I am wrong.

Thanks for your responses.

```

It's really two different bandwidths. Fs is determined by the bandwidth
of the signal. If you filter a 10MHz passband from a 1GHz signal, your
Fs calculation is based on the 10MHz of signal (if you choose to
undersample, which would clearly be to your advantage in a case like
this). However, since it's up at 1GHz, even though you might be able
to use a Fs > 20MHz, the ADC must have a sample and hold
bandwidth > 2GSps.

If your input signal has components from DC up to your desired signal,
then the two bandwidths are the same.

   25 years?  Probably about the same, since repeaters had been around
at least 10 years by then.  You could by a repeater over the counter
with tone squelch, and several other toys built in, so they were no more
complicated than a 2 meter handheld.  My high school Amateur radio club
built a two meter repeater of of Motorola and GE strips, homebrew powers
supplies, diplexer, and timers in the late '60s.  What is the big deal,
unless you have multiple sites and voting receivers?  We were just a
bunch of RF crazy teenagers with less than $50 to spend, and we wanted
to build a repeater. A few months later we were given a surplus WE Touch
TOne decoder module, and added a phone patch.

   Like everything else the club did, we raised the funds by repairing
old electronics and selling it to buy the parts we needed for the next
project.  the only new piece of equipment we ever purchases was a HW-16,
in kit form.  BTW, CW was the least used form of communications from the
club's station.  they could do that at home, but we had some nice
antennas, the two meter repeater, and several full coverage HF rigs.

Folks, all this stuff about Operating Systems is interesting, but it
doesn't apply that much to this "Homebrew Challenge" insofar as
the radio part of the radio station specified in the contest.

For only $50 in New Part cost, what does everyone think about
for the actual RADIO hardware?

Just curious...I have no interest in that contest...just a curiosity
of what might come up in the next year.

The Nyquist sample rate of Fs/2 is the minimum rate at which you can sample and theoretically recover the exact original signal. It's only theoretical, though, because recovery of the signal from the samples would require a perfect, "brick-wall" frequency response, flat phase response, low pass filter. Because we're stuck with using real filters, we have to sample at a considerably higher rate if we want to recover the original signal. Just how fast you have to sample depends on how good a filter you're willing to construct and how much distortion in the reconstructed signal you're willing to tolerate.

The bandwidth of an ADC can be limited by things other than the sampling characteristics, such as internal circuitry and packaging. For that matter, the distortion can also greatly exceed the amount determined only by quantization error.

Their goals of homebuildable and as cheap/functional as possible are in conflict. A starter homebrew design should be more modular, rely less on overloading of components for multiple purposes, include guidelines for substituting any expensive or rare part with found alternatives. It would not be concerned about requiring one of a part you can only readily get in bags of 10 or 20.

The cheapest possible starter 40M CW/SSB radio would probably be a kit,
not built from a collection of overpriced Radio Shack components. It
probably does a lot of work in the digital domain, without regard to
ease of modification. It's built on an etched PCB mass produced in
such quantities that it's cheaper than bare copper board at the local
electronics store.

Oh yes, I do intend to keep it up.
I am in the middle of building a TV transmitter with HB tuning caps built on
the PCB, but it is the modulator that is giving me a bit of a problem.

I have received the mail, and I shall reply to it shortly - very interesting
views: needs some thought :-)

Nice change to get some "inteligent" mail for a change. Usually I get 90%
SPAM, and of the rest it is 80% "I want" or 20% "I wanna complain".

Hey all,

I read about people using their sound card to catch transmissions
from dedicated senders such as SAQ by just hooking a roll of wire to the
mic-in and apparently finding some success in this. This got my wondering,
what aside from laws and fines is stopping me from hooking my 80W
stereo amp up to some sort of antenna for global transmission fun?
Somebody must have thought of this before...

It's cheaper to use your car alternator as an LO.
Upconvert by using the transmission as a mixer
and the gear shift knob as a band selector.
FM by riding up or down steep hills in a 2-cylinder Citroen.

Better yet, fax them copies of invoices of connector purchases from
competitors. Telling them "I'm not buying your product" means
nothing. Telling them "Because I hate your advertising, I am buying
your COMPETITOR'S products" means more.

Now that would be something. DX licence or driver's licence? Hehe.

Too bad I don't have a car. ;)

I agree, but I also think many will rise to the challenge, even though the prize is modest. Look for some very clever things--mostly done with IQ phasing techniques. I personally plan to enter with something, and suspect others on this list will as well. Also expect an even better project to follow that builds on all the best from the contest...I'm most interested to see what sort of frequency synthesizers/VFOs come out of this. I'm personally hoping ARRL gets enough entries that they can publish a book or something, and am hoping this will inspire some wonderful new kits and other things for newbies.

My design will not use IQ, will have a DSP (probably one of the
Microchip 30F4013s in a DIP pkg), but I haven't found/invented a VFO
scheme I really like yet (yes, I know the contest allows you to be
rockbound, but I'm shooting a little higher). I'll try to set up a
brag page and post progress.

I appreciate the time given for this contest--even with very spare time
people should be able to do something. I suspect ARRL's lab will have
their hands full testing everything that comes in (maybe they will
only test the finalists).

What fun!

73,
Glenn Dixon AC7ZN

>
> http://www.diamondsystems.com/slideshow.php3?name=ADBoardTutorial&page=4
>
> I am not sure why is this input bandwidth different from Fs/2. From the above link, one of the example has Fs/4. Is it just because to increase more precision that we use a sampling frequency 4 times the bandwidth of the signal?

They are different because they are two completely different things.

In a successive approximation or flash ADC the signal sampling happens over a very brief window, so aliasing happens over a very wide band. This means(for instance) that you could sample a signal at 10.25 times the sample rate of the ADC and have it come out at 0.25 Fs, assuming that your sampling jitter is small enough and your signal is intact going into the sampler at that frequency.

The input bandwidth of the ADC is just the bandwidth of the ADCs circuitry leading up to the sampling stage. In principal it could be just about anything. In practice SAR and flash ADC's have relatively wide input bandwidths, while sigma-delta and slope converters have input bandwidths closely matched to the sampling rate.

>
> I assume for practical reasons, we oversample it but that is for more precision (correct me) but the Nyquist criteria still holds good for sampling the frequencies upto Fs/2. That means I can still get the original signal. I am not sure about the accuracy though.
>

Theoretically the Nyquist criteria holds up to Fs/2. Practically you need to oversample at much greater frequencies than that, or sweat blood on your anti-alias filters.

>
> Also, can I say that if an ADC is oversampled 4 times the Nyquist rate (Fs = 4*BW), then is my input frequency given by Fs/4? Assume single channel case.

You can say that your bandwidth is given by Fs/4. Your input frequency depends on the characteristics of your input signal, which may be quite different from the characteristics of your input filter.

What is stopping you?

Well, the laws of physics for one, but you're welcome to give it a
try. You'll find enforcement of those laws is pretty strict. :-)

Engineering is the application of physics. An "engineering perspective"
is one that starts from knowledge of the basic physical principles
involved, and uses mathematics along with that knowledge to produce a
design or solve a problem. I've seen no evidence of either in your
approach. Whatever you're doing, it's certainly not engineering.

The main problem with what you propose is that the electromagnetic field you create with the amplifier will be small to begin with, and it will be attenuated rapidly with distance for a number of physical reasons. But don't take my word for it. Crank that dude up, and don't stop at 11. Broadcast your telephone number and wait for the phone to ring.

Hm. I was a student of IT on a polytechnic... The basic state of mind one needed there was that we don't need to know all the facts by heart, but we must know where to find them.
In this case through a few degrees of separation I had specs which say that it doesn't need to be efficient; it only needs to work. Then when I have it working I can begin identifying bottlenecks and come up with ways to widen them.

Good info on magnetic field strength there, thank you. It gives me a good idea of where to start looking and comparing.

I'm not going to experiment just yet since I'm not a radio amateur, though I'm vying for a licence. The radio-regulatory authorities here in Finland don't have much to do, so I'm not going to give them a reason to hunt me down. :o)

No. The problem is that wavelength of a, say, 10kHz signal is 3km in free space. You need to have an antenna that's a decent fraction of that length for the antenna to look "distributed" enough (that is, the phase of your 10kHz signal at the far end of the wire is significantly different than that at the near end) in your to start getting any radiation. You can go through the math for all this -- look up the input impedance of a short dipole on Google -- and you'll find that the radiation resistance of a reasonable length speaker wire is probably going to be in the milliohms, yet the finite (real) resistance of the wire is going to be 10-1000 times as much, and the reactance will be as well. Hence, all three parameters are against you: The high reactance will keep the amps from being able to put much power into the cable in the first place, and of what does get there, the vast majority will be eaten up as heat rather than radiating.

To make matching tenable (so that you can actually get power into the cable), you need a *very* long wire. To make things efficient, you need low loss conductors -- nice, thick metal rods. Hence, doing a good job becomes rather spendy, and thus you don't see that many people outside of the military building VLF systems.

I think I'd almost suggest trying something like a 1.3GHz moonbounce system prior to building your own VLF transmitter...

I built a noise source as described by Bill Sabin, W0IYH in QST (1995)
and EMRFD. Works fine, but now it's time for calibration. Chatting with
Bill, he reinforces the notion that the best way to go is comparison
with another calibrated source, or a direct measurement with a

calibrated noise figure test set. NoiseCom used to provide this service
to hams for <$50, but now they claim they have dropped that offer (it's
about $600, now). So my question is, is there anyone in the SF Bay
Area (I live in Livermore) who might be able to help? If someone owns a
source or test set, perhaps we could get together. I'm open to other
suggestions, too.

FYI, this is primarily for testing HF rcvr performance. I'm building an
R2-style DC rcvr, and it's turned into a nice research and education
project, so I go a bit overboard sometimes, but it sure is fun. I'm
also using an IQPro DDS VFO. I wrote a couple reports on its
performance that are up on the AA0ZZ website.

This is my first post to this group. There seem to be a lot of talented
folks lurking out there... Thanks in advance for any help.

73,
Gary, WB9JPS

Possible, but with more distortion (oops, he calls it compression) than he claims.

I'm not sure, but at HF, can't you get a reasonable noise performance measurement by pushing the radio off the bench and using a Radio Shack sound level meter?
</sarcasm>

Sorry.

At least previously, the frequency tables started at 9 kHz, so anything below that would not cause any interference to any other service.

However, the problem with VLF is that any practical antenna is going to be very short compared to wavelength and since the radiation resistance is proportional to the square of frequency for antennas well below 1/4 wavelength, most of the power injected into an antenna is going to be dissipated in resistive losses.

At the LF aeronautical beacon band with 90 m antennas, the antenna efficiency based on measurements flown around these beacons seems to be about 1 %. In Europe, the maximum _radiated_ power limit on the 135 kHz amateur radio band is 1 W, but generating that kind of radiated power with reasonable sized antennas (30 m) would require at least 1 kW of transmitter power, indicating that the practical antenna efficiency is about 0.1 %. At 13 kHz, the efficiency would be about 0.001 %.

The near field distance for a simple antenna extends to about 1/6 wavelength, so at VLF, the practical communication range for amateur communication systems would be well within the near field.

Since you are apparently from Finland and since the Finnish telecommunication law only grants the jurisdiction to the telecommunication authorities for "freely propagating" electromagnetic radiation, my interpretation of the law is that it does not cover any near field i.e. magnetic or electrostatic communication systems, in which the near field communication systems work.

Of course, if you are able to generate huge magnetic or electric fields that cause interference to other systems, this may cause problems to you.

But otherwise, go ahead with your experiments, but unfortunately the laws of physics will hit you sooner or later :-).

Thanks, that's what I was afraid of. I, too, use it for rtty, packet,
amtor, pactor, etc. but I was looking for a way to use the fax and sstv
modes. It sounds like I might be out of luck, maybe I can find a sound
card program to do those modes. I guess worst case I could find my old
software and load up dos on an old machine if I can still find it all.
MFJ doesn't seem to support it anymore, they don't seem to have any
windows software for it.

Thanks,
Kerry, WD5ABC

>I built a noise source as described by Bill Sabin, W0IYH in QST (1995) and EMRFD. Works fine, but now it's time for calibration. Chatting with Bill, he reinforces the notion that the best way to go is comparison with another calibrated source, or a direct measurement with a calibrated noise figure test set. NoiseCom used to provide this service to hams for <$50, but now they claim they have dropped that offer (it's about $600, now). So my question is, is there anyone in the SF Bay Area (I live in Livermore) who might be able to help? If someone owns a source or test set, perhaps we could get together. I'm open to other suggestions, too.
>
>FYI, this is primarily for testing HF rcvr performance. I'm building an R2-style DC rcvr, and it's turned into a nice research and education project, so I go a bit overboard sometimes, but it sure is fun. I'm also using an IQPro DDS VFO. I wrote a couple reports on its performance that are up on the AA0ZZ website.

If you can't get a calibrated comparison noise source, here's some tips on workshop calibration techniques on random noise:

Random noise voltage or current can ONLY be calibrated by a TRUE Root Mean Square measuring instrument. By "true" I mean a thermionic type such as an RF power meter (thermistor, bolometer, etc. sensor). Few voltmeters on the market have TRUE RMS measuring capability; those that do are specified as such and rather on the expensive side.

A very low-level random noise source can seldom be measured directly by an available-market voltmeter or power meter.* To calibrate it with such instruments requires amplification. A receiver can provide that - provided - it is carefully checked for linearity. By linearity I mean one that does not clip or saturate the RF or IF or detector. A wideband TRUE RMS voltmeter can measure the last IF output and do a comparison between IF signals from a signal generator and the random noise source into the front end. If the front end noise is significant, the total noise input-equivalent will be the good old square root of the sum of the squares of the noise sources; knowing the true RMS values of both and just one will let you find the true RMS value of input noise voltage of the unknown. [kind of nuisance grunge work but then most metrological work <calibration> is of that nature :-(]

* Jim Williams of Linear Semiconductor had a nice article in EDN a few years back, pushing a Linear Semi true RMS IC. In

that was a list of available "RMS implied" voltmeters with their sensor types stated. The cheapo averaging circuits in common multimeters could be LOW on true RMS voltage readings down to half of readings (despite their stated accuracy specs). The Linear Semi IC apparently didn't sell well and was taken off of active production. Perhaps only National Semiconductor has a rough equivalent?

>This is my first post to this group. There seem to be a lot of talented
>folks lurking out there... Thanks in advance for any help.

Living in southern California I don't get up to mid-state often. Difficult to drop over with a comparison source. :-)   However, a bunch of us lurking in here have been "around the horn" a few times and we can supply a few items of information to help. [or maybe to add to the "random noise" level? :-)]

Hi Doug,

I could load a diagram for an amplifier in the files or photos section of the yahoo rfamplifiers group if you'd like. Post a want over on the group and we'll help where possible. No problem putting a 4-400 on 50 MHz.

http://groups.yahoo.com/group/rfamplifiers/

cheers,
skipp

   No damaged traces, but someone covered the exposed terminals with
black electrical tape over the HDE15 knockout.  The 15 pins aren't too
hard, but removing the two spring loaded mounting clips is the bear.  If
the onboard video is bad, I'll remove it and put one of the old DE-9
filler plates over the hole.

Hello there,

Ham Radio Outlet sold a single knob cw keyer in the late 1970's and early 1980's.   The front panel control was only the speed adjustment and power on/off. It's a small black painted box about the size of a sardine can and the rear exit wire connections are routed to an iambic style key. Runs of an internal 9 volt battery and has no side tone.

I'm looking to buy one in any condition (even parts of one).

Please just the described "HRO" or "Ham Radio Outlet" keyer is all I seek. I have other keyers in my collection already but this keyer is the missing link from an original ham station a friend and I used to operate. We'd like to duplicate that station now with the original equipment where possible.

Sell outright or trade..? your choice. Please contact me below if you have the mentioned keyer for sale. Please no other spam or solicitations.

thank you
skipp

Yes, that's the ticket, back to the past. As if enough people weren't
abandoning ham radio already. I have never thought that code was
essential. It is just another "hoop" that someone has to jump
through. Once I passed the code test, I never used it again. Get
real, this is 2006, and with all the innovations on the radio
spectrum, code is the last thing on people's minds.

If there is ever a serious emergency, including no commercial
communications, guys like you who can't build a simple transmitter and
companion receiver, and can't do code, will be the first to scream for help.

What makes you think people are abandoning ham radio?  I don't see that at
all, but I do see a reduction in new hams.  But...... What goes around will
come around.  Ham radio will grow again if the ARRL will quit mucking it up
with their friggin yuppy, elitist attitude.

Don

when was the last such emergency BTW

For that matter I have built voice tranceivers am I admit

The ARRL trying to represent either the interests of its memebr (the
code forever crowd or those of the ARS would help

Where did you get the part that I cannot build a radio?  I simply said
that I do not use code anymore!  I have built many radios, repaired
them and use them to this day!  This attitude is typical of
old-timers, and I am 54 myself!  How may radios have you built pal?

I agree with you on the ARRL!  They are the ones who constantly keep
pushing for "code" requirements to be raised!  Check the figures on
hams around the country.  At a recent South Florida hamfest, it seemed
that I was the youngest guy there!

I went to ham fest couple of months I was the youngest guy there at 42
no less my wife shal we is 29 was still the youngest and had the least
number of reps on that 29th birthday

Well, if that's the case, why not test them on use of the new innovations?

How about making them demonstrate competence operating five different
modes of their choice? They can choose between HF SSB, VHF/UHF FM, CW,
SSTV, fax, RTTY, packet, what have you. That way folks who want to learn
code and might use code have an advantage, but folks who can type 130 wpm
also have an advantage...

five direferent modes might eb a bi much but in any event it is
impractical

It is just another "hoop" that someone has to jump through. Once I passed the code test, I never used it again. Get real, this is 2006, and with all the innovations on the radio spectrum, code is the last thing on people's minds.

Dumbing it down cheapened the license, making being a radio amateur nothing special. No wonder they leaving.

Scott,
I agree with you! It is organizations like ARRL who continue to
insist on Code! Keep up with the times and test over what is current
and actually being used. I have a restored 1940 Chrysler but I also
have a 2005 PT Cruiser with A/C and all the options. I enjoy the
1940, but I would not take it on a cross-country trip.

I've been off the air for several years and am getting back on finally.
  I have an MFJ-1278B TNC and have used it with a normal terminal
program on Windows (hyperterm) and Linux (minicom) but don't have any
software anymore that will run on XP or Linux. Is there any software
out there that supports the other modes this TNC will do like wefax and
sstv? I have used it for rtty, cw and packet but don't have anything
that will work with the graphical modes.

Any suggestions? Will any of the sound card software work with a TNC
instead of a soundcard?

Thanks,
Kerry, WD5ABC

Thanks for the info.....................I've already got an 8558B, so I am set. I just removed the knobs for some extras for my own unit. I don't have much tied up in this unit, and I have already scrapped it.

Pete

> Dumbing it down cheapened the license, making being a radio amateur
> nothing special. No wonder they leaving.

=================================

Why should anybody be 'special' for being a radio amateur .
AR is for most of us just a hobby ....a hobby involving lifelong
learning on a huge range of radio communications related topics.
It is a hobby for anybody interested in 'Communicating' by radio,
whatever the level of past education.

Sadly a number of AR licensees see the hobby as one reserved for the 'elite' and look down upon those with ,what they consider, a lower level ,even inferior , license.
I fail to understand why superior skills in receiving and or transmitting Morse telegraphy would make anybody a better Ham ,considering the other aspects of the hobby ,like emergency comms (mostly without Morse telegraphy), satellite comms , propagation study ,digital modes and ......homebrewing ,just to name a few.

The above referred elitist's attitude towards the hobby is not just apparent in the USA but also in Britain and many other European countries.

Hi all,
I have had a bit of a busy half-year, with sickness in the family and the like. But I have managed to add a few new projects that could be of interest to my homepages on http://web.telia.com/~u85920178

Have you ever wondered how these old IF-cans can be re-used? I have two different articles dedicated to them:
http://web.telia.com/~u85920178/begin/cans-0.htm (reusing IF cans)
http://web.telia.com/~u85920178/rx/tda7k-rx2.htm (TDA7000 for NBFM)
http://web.telia.com/~u85920178/blocks/if-txfmr_tube_00.htm (Making your

own)

Last month someone asked me how I choose values for components, but "Can you add calculations". Ok, I did it, with a few over-simplifications, and for a crude project:
http://web.telia.com/~u85920178/begin/bug_calc.htm (FM Wireless Microphone)
http://web.telia.com/~u85920178/begin/calc-00.htm (Includes loads of useful calculators)

Earlier int he year I needed to throw together s quick VHF antenna for 446MHz, 432MHz, and again for 145MHz. When I had to do it for 105MHz I created this project:
http://web.telia.com/~u85920178/antennas/vpole0.htm (15-minute +2.5dBd antenna)

Where did those multi-gang tuning capacitors go? I needed one, so I etched it on a PCB, cheap:
http://web.telia.com/~u85920178/use/tuning_caps.htm (multi-gang - for HF/VHF)
http://web.telia.com/~u85920178/use/tuning_caps2.htm (PCB Preset capacitor)

If anyone can help me get the supplier and part number for "hobby time" I couild use a bunch if it ;-)

Best regards Harry

>1940, but I would not take it on a cross-country trip.

Well, the argument is that you have to do _something_ to ensure that people
licensed are competent operators and have some usable skills. I think the
code requirement is not the best way of doing that, but it's better than
nothing. The only alternative I ever seen proposed is just that, nothing.

So, I am in favor of dropping the code requirement, IF it can be replaced
with something else that helps ensure licensed operators are competent and
skilled.
--scott

But then, I _would_ take a 1940 Chrysler cross-country.

I'm not against having good hams, but can you tell me what your Inane proposals have to do with that. Over 30 years I've seen tons of 20WPM Jerks on the bands. CW has nothing to do with the people we get in.

I'll bet that most of the folks "leaving" are simply not renewing being SK. Code is in a way a dying art quite literally. Which is a shame.

We have to face it, this hobby doesn't attract a lot of new blood and the existing stock is rapidly growing older. The advantage to me is that I can find old ham equipment at estate sales for next to nothing but that's not what I'm posting about.. :)

I don't think things are all that "unfair" with the maximum code speed we currently test being 5 WPM. Of course that's what I got tested at so you can charge bias if you want. I currently don't operate CW (heck, I don't operate at all right now) but all that spectrum space in the lower part of the bands is starting to beckon. I've got a code practice program and I work on my code from time to time so maybe someday...

So where do I fall in this debate? I certainly don't favor the removal of the code requirement for all license classes. Extra's surely need to be tested at the current 5 WPM. But the fact remains that the interest in this hobby as shown by the decline in the number of licenses needs some attention.

We don't need to "dumb" down the hobby to get more folks in it, but we do need to bring the requirements into the current age. Before the advent of the personal computer 20 years ago, it would have been very expensive to set up an automated CW send and receive station, but now you can do it for next to nothing. One can actually send and receive CW without ever learning it and get transmission rates much faster than just about anybody can copy by ear, just hook up your PC to the rig load the software and voila, the no code licensee is sending and receiving at 25 WPM the day after he failed the 5 WPM test.

On the other hand, you guys that struggled to get their code speed up to 20 WPM so they could get their Extra have my respect. I understand that lowering that requirement seems like we are dumbing down the hobby, but I hope you can understand that like AM, CW is being replaced by other modes that you and your generation have pioneered.

My greatest fear is that the FCC will totally do away with code in it's testing requirements, which will logically lead to a mass spectrum reassignment to make more room for voice and we will likely loose our valuable spectrum space in the process. But once the last license goes to SK what's to stop the FCC from giving it all away?

May code never die, there are times it's the only option, but we have to keep the hobby relevant or it will all go away when the hobby dies.

I don't think the code require is necessarily "unfair" somehow, but it does seem awfully "arbitrary" these days. In *today's* world, it's just one mode of many, and a rather unpopular one at that.

> So where do I fall in this debate? I certainly don't favor the removal

If we're going to make people show a certain commitment to amateur radio before giving them advance privileges -- reasonable enough --, to me it seems that the study should be of something more people are likely to use... say, error correction coding theory, or modulator design or something. Or maybe something even more practical such as demonstrating the ability to perform link planning (antenna selection, power selection, etc.). I imagine one of the reasons CW testing remains is because it is so easy to test compared to those options.

I think I'm pretty much in agreement with you... 5 WPM is not an unreasonable barrier to entry, and I don't particular oppose keeping it around, but I do think it seems awfully arbitrary, and this refelcts somewhat poorly on hams as a group trying to present themselves as modern and professional.

I was under the impression that CW would get through under worse conditions and/or with lower power requirements than other modes.

Does no one run "flea power" anymore?

I sometimes listen in on 10 meters but don't hear much there. A bit of CW every now and then, but not much of anything, usually. Maybe I'm listening at the wrong times? Or is it mostly vacant and just freebanders buying the 10 meter rigs?

Scott,
I took the 1940 Royal Coupe on a mini-cross country trip here in
Florida, managed 60-65 with the overdrive, the original factory AM
radio pulling in at least 10 states, remember those days!  Got about
19-21mpg with the old flathead 6, but the 2/60 A/C wasn't really up to
snuff.  Once I opened the cowl vent and the vent windows turned all
the way in on us, it became tolerable.  Waiting for the winter months
here in Florida to really enjoy the old car.

Well, one of the nice things about code is that you don't _need_ very
much bandwidth.  And with modern DSP you should be able to make IF filters
even narrower than my old R-390... should be possible to cram hundreds of
carriers into the space of one SSB channel.

And hey, what's happening to the 500KC marine allocation?  That's pretty
much dead... I wonder if the ITU could be convinced to give that to the
ham radio operators.  Nobody else wants it.

>May code never die, there are times it's the only option, but we have
>to keep the hobby relevant or it will all go away when the hobby dies.

I don't think code ever will die, but I could see a world in which it is
even less relevant than it is today.  That's not to say we shouldn't encourage
its use.

So true, and low bandwidth helps CW get though when SSB would be impossible. However, don't forget that CW can be done quite nicely with a cheap computer, some simple cables and some free software without learning it. I suppose that one could argue that a human ear can hear what a computer can't, but I'd be willing to argue that point in favor of the computer.

I'll be willing to bet that there won't be much improvement over CW in the raw "get the message though under bad conditions" power with the new digital modes using the same bandwidth as CW. Simple is under-rated in my book.

As an operating mode CW is alive and well and likely to stay, however it will be computer driven more and more as the art dies off and new blood is not required to learn it as well as the old.

Change is neither good or bad, it's just change.

So true, and low bandwidth helps CW get though when SSB would be impossible. However, don't forget that CW can be done quite nicely with a cheap computer, some simple cables and some free software without learning it. I suppose that one could argue that a human ear can hear what a computer can't, but I'd be willing to argue that point in favor of the computer.

I'll be willing to bet that there won't be much improvement over CW in the raw "get the message though under bad conditions" power with the new digital modes using the same bandwidth as CW. Simple is under-rated in my book.

As an operating mode CW is alive and well and likely to stay, however it will be computer driven more and more as the art dies off and new blood is not required to learn it as well as the old.

Change is neither good or bad, it's just change.

Has much to do with where we are in the sunspot cycle. A couple or three
years from now
10 meters will start to be much busier. It's my misfortune I got my upgrade

to General a year before the dead bottom of the cycle. At the age of 74 I'm
just hoping to be around long enough
to see what the high point in the cycle sounds like.(G)

Yes that can be true.  They speak of PSK as being low power but that is only
low transmit power.  It takes more power to generate a 25w PSK signal than a
100watt CW signal.  Computers draw a lot of power.

> Does no one run "flea power" anymore?

There are a lot of QRP (low power) hobbyists.

Bad point in the sunspot cycle for 10 meters.  It does open occasionally but
not like it does at the peak of the sunspot cycle.  Right now it is not open
every day (although it may be open for a while each week).  And the time of
day it is open tends to be when people are working, doing errands after
work, etc.

>

Actually, you would lose such an argument. There are many hams who have proven that they can decipher better than the computer. The computer hardware or software requires the following characteristics in the received transmission to work:

1. A strong signal
2. No distortion on the signal such as occurs from aurora, meteor scatter, etc.
3. The code sent is nearly equal in quality to that sent by a computer. Some one using paddles may achieve that but if they are sending with a manual key or bug, that is highly unlikely.

I have frequently been able to copy better than the computer and my code skills are quite modest. The only time it beats me is when the code meets the above three criteria and is too fast for me to copy.

While change is neither good or bad, sometimes the results of change can be undesireable.

   Enjoy!  :-)

   Everyone else ought to remember the definition of ham:  "Ham is
   the butchered meat of swine."

   There...now THAT's a troll!    :-)

Where I once worked..we used a chemical stripper that we brushed on
fine enamel wire.
The insulating enamel would then wipe off. Earl VE3AB

Solder strippable wire is also called "Bicelflux wire" and it's a polyurethane enamelled heat removeable insulation. Long ago, I bought several small putups from a no longer remembered US supplier, however, among others, it's available from:

http://www.greenweld.co.uk/acatalog/Shop_Enamelled_49.html

in a variety of wire sizes.

When the insulation is removed with a dollop of molten solder, a toxic gas is released (in small quantities to be sure) and it ought to be done with good ventilation in the workplace.

Hi,

I am reading the ARRL Handbook on Receiver Design and frankly, I find
it's a bit out of my league.  The writing assumes some knowledge of
circuitry that I am weak on.  Eg., I think I can I can see from the
schematic that an RC circuit is shifting phase in a quadrature amplifier
stage but it's not mentioned in the text as such.

Hopefully, someone out there can get a sense of where I am on the
learning curve and can suggest an appropriate text (not TOO basic, I guess).

Thanks!

John

hello all,

i need the rf board from a ten tec 509 rig. i had one follow me home but the rf board is missing. i called ten tec and they have all the parts for the board, they just no longer have the board. i am planning to build the final on perf board if i can not find one from a parts rig. the board or rig does not need to be working. i'll fix the board, just wanted to save a little time. any help appreciatred. 73 mike ku4yp

Good tip, Frank! Thanks but I've tried that before. Depends on the
polymer of the knobs...some can take moderate flexure (usually
polypropylene?) but others (polystyrene) can't.

   Thank you Dan (you spell the surname correctly!).  :-)

   "Red Spirit?"  Unfamiliar term to me on this side of the pond.

   I've tried Toluene and MEK and found them lacking.  Turns out
   that (in varying percentages) are part of the paint stripper goop
   sold in do-it-yourself stores over here.  I can get Ethanol and
   may try that.

   In years past, the General Cement Company of Rockford, Illinois,
   had a blackish goop they marketed for stripping magnet wire.
   Worked extremely well, dip once, let it sit for a minute and the
   enamel coating can be seen to actually lift off of the wire.  One
   wipe and the wire surface is free, ready to solder.  Had a
   definite acid content from the smell of it (sharp, acrid).  The
   tradename was either "Strip-X" or "Strip-Var," not sure which
   now.  :-(   Mine was used up years ago, bottle tossed out.

GC Electronics "Strip-X", I assume? I found a MSDS which states that
it's 70% methylene chloride, 25% cresol (isomers of cresylic acid),
around 5% ammonia, plus some wax and thickening agents.

One poster stated that it was designed to work with Formvar
insulation, and might not work as well on the newer Polythermaleze
insulation.

I don't see it in their current catalog... probably gone where the
goblins go, yo ho!

I had occasion recently to wind a couple coils. Checked my stash and found two different kinds of 30 ga enameled wire. I thought I'd try tinning the ends of the wires without stripping. One of the wires soldered very easily in a few seconds so must have been heat/self-stripping. The second sample didn't solder as easily, but I kept the wire in ball of molten solder for 10's of seconds and eventually the enamel melted off and formed sludge on the surface of the solder ball. Cleaned the corrupted solder off the iron tip and the wire tinned up ok.

Not sure if the second one was normal enamel or just a slower version of self-strippable wire. Might be worth trying to just melt the enamel off in a ball of solder like I did.

There are two totally different families of enameled wire, and the original question didn't say which one.

For the pretty-coloured polyurethane enamels, solder stripping is the way to go. As Harold says, that is how they are designed to be stripped. Professionals use a solder pot, while the rest of us make do with a big bead of molten solder on the tip of the iron. Don't use a flame for solder-strippable wire - it's too hot, and charred polyurethane enamel sticks to the wire.

Heated for long enough at the right temperature, the enamel comes right off with no scraping required. The decomposing enamel also acts as a solder flux, so the stripped end is bright and ready-tinned.

The other type of enamel is usually brown - some of it is your grandfather's brown lacquer, but the modern stuff is not.

The really old stuff can be charred in a spirit burner (chosen for its cool flame which doesn't oxidize the copper) and the loose carbon scrapes off easily. Note: this is the *only* kind of enamel that is suitable for flame stripping.

The modern brown enamels are totally different. They are mainly intended for motor and transformer windings, are often double-coated, and are specifically designed to be heat-resistant and tough as old boots. They are almost as tough as the copper underneath... and there's your problem in stripping it.

This stuff laughs at molten solder and spirit burners. Heat stripping is no good because flame temperatures high enough to decompose the enamel will also oxidize the copper underneath. As far as I know, the only ways to remove it are by scraping, sandpapering or filing... all of which are difficult to do without nicking the copper wire.

So how do the professional winding shops do it?

GM Ian, guess you're getting used to the Highlands by now. Had a great trip to Scotland for 3 weeks in June, Blair Athol to Glencoe. Not long enough though. Yes, Polythermaleze and heavy polythermaleze and Formvar are the chrome vanadium steel of insulations. If you want to wind wire tightly around a faceted diamond without damaging the insulation, those are what you use. Basically, One divided by Bicelflux.

Professional winding shops invest in a machine that looks and operates somewhat like an electric pencil sharpener. It abrades the insulation and is automatically set for each different wire size. Needless to say, they come a bit dear. (Not as dear as diesel fuel in Pitlochry, but dear!)

Regards
W4ZCB

I posted a picture of a very useful hand stipper I have been using for
about 24 years, See it on alt.binaires.schematics.electronics under
"Wire stripper for RRAH".

I suggest "Experimental methods in RF Design" if that is not the one
you are using... If it is the one, you need to start by building a few
of the basic blocks, RF amp, Mixer, IF amp, AGC, etc. one at a time and
then combining them...

Depends a lot on the type of "enamel" that you are dealing with. As noted
elsewhere, some is fairly simple to do with hot solder and some is resistant
to thermonuclear techniques.

I've been successful with one of two methods on most of the stuff.

As noted, a solder pot (fairly cheap, by electronics tool standards) will do the job nicely on 90% of enamel wire.

Or, a professional paint store (NOT HandyAndy) has a parTICularly nasty chemical paint stripper called "Aircraft Paint Stripper", mostly methylene chloride which is highly toxic. About five minutes soak in that would strip the chrome from a trailer hitch. Don't sit in a spill of the stuff or you'll be talking in a high squeaky voice for the rest of your life.

Jim

Depends a lot on the type of "enamel" that you are dealing with. As noted elsewhere, some is fairly simple to do with hot solder and some is resistant to thermonuclear techniques.

I've been successful with one of two methods on most of the stuff.

As noted, a solder pot (fairly cheap, by electronics tool standards) will do the job nicely on 90% of enamel wire.

Or, a professional paint store (NOT HandyAndy) has a parTICularly nasty chemical paint stripper called "Aircraft Paint Stripper", mostly methylene chloride which is highly toxic. About five minutes soak in that would strip the chrome from a trailer hitch. Don't sit in a spill of the stuff or you'll be talking in a high squeaky voice for the rest of your life.

Jim

I dunno if anyone here is good enough to know, but it's worth giving a
shot... I stumbled on a website
(http://mikroelektronika.co.yu/english/product/books/rrbook/chapter4/chapter4a.htm
)on how radios work, and how they can be made with various IC parts, I
studied the IC parts in question (via datasheets and stuff), and came
up with a plan for a radio that runs in stereo on both bands:

http://i9.photobucket.com/albums/a77/Rover_Wow/AMFM.png

I know the voltage is sound (4.5-6.0 V), but how good would it work,
and how much would it cost to make?

Those writing "popular" (including ARRL) tech books are told not to include any equations for better or worse. The ARRL books are not bad as cookbooks but they skip a lot of steps leading up to understanding why all those parts are there :-).

If you are looking for good readable books that build up from basics and do not shirk at all from equations/analysis/calculus, try:

The Art of Electronics, Horowitz&Hill, for general electronics and a tiny bit of radio. Begins to do noise analysis, PLL's, etc.

Communication Circuit Analysis and Design, Clark&Hess, for excellent

RF/mixer/modulator/demodulator stuff.

Tim.

Wes Haywood and his buddy have forgotten more about working electronics than many of the published authors will ever know... I have used and modified parts of their circuits for decades... I still find somehting new to play with everytime I dive into my dog eared copy... Enjoy...

One of the best books, if you can find a copy, is "Solid State Design For The Radio Amateur" that was published by the ARRL in 1977, written by Doug DeMaw and Wes Hayword. It covers theory and modeling, as well as practical hands on building of RF receivers and transmitters. (Why the ARRL doesn't re-publish this great book is beyond me...)
On a simpler level, any of the the "Notebook" series of books by Doug DeMaw is a good place to learn about practical RF circuits and radio design.

Contact Ten-Tec again and see if they have the "Gerber" files archived somewhere and will send them to you so you can have a board made. Send the Gerber files to any of the board houses and they will make you a board to match. May be a little costly for just one board.

I would suggest "Solid State Radio Engineering" by Herbert L.
Krauss, Charles W. Bostian, and Frederick H. Raab, John
Wiley & Sons, 1980. It covers radios for a lot of radio services,
isn't confined to amateur radio practice. Hardcover 534 pp.
Check used book listings on Amazon. Not one for Basic
Training but its not for PhD studies, either. Solid information
(no pun intended). It has nice illustrations. :-)

ARRL has announced a design competition that some of you may not have heard of. The objective is to produce a CW and SSB transceiver with at least 5 watts of output on 40 meters. Components must be commercially available. The total cost of all components (except key, mic and power supply) must not exceed $50. Any instruments beyond a multimeter must be in the $50. Complete information is at http://www.arrl.org/qst/hbc/. Credit for the original idea goes to N4AUP/9. All components of the entry must arrive at ARRL by next August. The winning entry will be the subject of a QST article.

I would hope that the winning entry would also appear in the ARRL Handbook and the "Now You're Talking" book. It would also be desirable for this contest repeat every two years, alternating with an SSB/CW transceiver for a single VHF or UHF band, or perhaps for two bands most suitable for working the low-orbit satellites: something worthwhile for new Technicians to build (such a competition might have a higher limit than $50).

The idea that new hams could again build their own stations using money earned after school is very appealing. That was a plausible objective in the 1960s, because of the availability of components from obsolete TVs.

Tom, N3IJ

Good morning all. I picked up a sweep generator at a local ham fest. A
Knight KG-687 Sweep Generator. I figure that I would give it a try for some
tough alignments beloved tube type equipment (e.g.. Hammarlund HX50
Transmitter). http://www.ppinyot.com/hammarlund.htm Restoring and aligning
this beast is kicking my butt. Getting the RF amplifier and mixer stages
balance ("linearized" or leveled across the dial) over the US allowable BW
is very difficult. I am hoping a sweeper can aid me in this effort.

So I went and bought my self two sweepers. The above referenced Knight and
an EICO. Both have identical control ranges and functions. But no
schematics. Only a Knight Ops manual.

Any help would be appreciated. The Knight is not on BAMA (unless I missed
something).

Thanks,
Paul P.

Subject says it all... (or nearly so)

Looking for a 756ProII display, as the one of my radios has a bad one (looks like horizontal sync has gone south...) Icom wanted a bundle and a half to replace it. Want to fix it myself, but don't have access to enough test equipment to debug the one in the radio at present, so looking for a replacement display. Would even consider a homebrew type of solution (currently using the radio as a computer controlled radio, but I'd really like the display to work too...) If someone has information on the actual display data stream so I could homebrew an adapter to convert to a vga or even a laptop display, I'd be grateful...

Barring that, am looking for other sources of the original display. Anyone got one, or a dysfunctional 756Proii that you'd sell cheap? Located in Hawaii, so can't get to the swap meets and such... Best shipping method to here is USPS Priority mail because it's not expensive and gets here in decent time.

Thanks

I have a collection of "wall wart" (others may call them "transformers")
and I'd like to use one to cobble a little power supply.  I've never
opened any to see what's really in them (and suspect it'll be quite a
chore), but I'm quite sure they are not ALL "transformers", because some
claim AC and some claim DC output, yet the first I grabbed out of the
junkbox claimed DC AND ALSO provided a HEALTHY AC output on the same
two wires!  Furthermore, NONE of them seem to be voltage regulated!
(But if one says "X volts at Y milliamps", then loading it to Y mils
usually gives an output close to X volts.)

So what IS in them?  Do the really light-weight ones, for example,
use a capacitor for relatively low-loss voltage dropping?  And
why would one give *BOTH* AC and DC?  Bad diode(s)?

It depends...

The AC ones are just a transformer.

The DC ones contain a transformer and diode(s).

The cheapies usually don't contain any capacitors or regulators, hence
there is significant AC on the DC.

I know you're not.

I was jabbing Lennie in the ribs about supposedly not finding someone (you?) under a certain call when HE'S not in there either. Never has been.

Sorry for the confusion.

Steve, K4YZ

And AFAIK most of them achieve current limiting by intentionally making
the windings lossy, so you can't burn down your house by shorting the
leads together.

------------ REPLY FOLLOWS ------------

Agreed, those are among the best variable capacitors ever made.

My first radio in 1957 was an ARC-5 a friend gave me. It had a shaft made from a piece of 1/4 inch copper tubing, carefully drilled out so it was a very tight force fit. No glue, set screws or anything like that, just a very tight fit that had to be driven on with a hammer. I used that RX for a couple of years and the shaft performed perfectly.

Hope this helps.

Bill, W6WRT

There are also some transformer-input types that produce well-regulated DC
outputs using linear regulator technology, and a growing number of units
that use switching regulator technology to make the transfoprmer so small
that it's hard to tell from the outside that there's even a transformer in
it.. The latter are easily distinguishable because they put out quite a bit
of power, yet are smaller and much lighter in weight than traditional units
with equivalent power capability.

Such units actually have a bridge rectifier across the AC mains and
supply DC to a switching regulator running at 20-50khz. There is an
isolation transformer running at this frequency (it's core is just a
small bit of lightweight ferrite). The output of the isolation
transformer feeds another bridge rectifier and filter (at ~40khz not
much of a filter is needed, small caps and chokes!). There may then
be a linear or switching regulator. If the later, it may actually
regulate by changing the switching frequency/duty cycle of the
original switcher at the AC mains input. In this case the feedback
is by means of an opto-isolator for safety.

I would take exception to the "windows" requirement for the PC. They
should allow a solution using both "MAC" and "Linux" based PC's
especially the later. Linux can run on a 'throw away' computer that is
now underpowered for current generation Windows OS. Also Linux is FREE

(perfect for a budget project!).

I don't run windows on my computer. Currently running Gentoo Linux, but
for non-computer gear heads I recommend Ubuntu, Kubuntu, or Xubuntu Linux.

Years ago in 73, and other mags, programming an eprom for the Icom 22S
was the rage.
I now have aquired a TransWorld transceiver that is programmed with
diodes. I wish to build a BCD thumbwheel input, with an Eprom for data
translation. It's no problem building a board, but it's a problem with
me programming the eprom. I don't need anything fancy, no memory, no
scanning, just using the thumbwheels to move frequency. I've never
programmed an eprom before.

> especially the later.

Evidently, you didn't read this requirement thoroughly.

"The software must run on a Windows based PC platform although multi platform support is encouraged."

I assume this is to make sure a solution is not done soley on an apple or linux box, thereby leaving out 95% of computer users. I'm a linux user, but let's face it, not including Windoze would exclude way too many people. Not good for promoting ARRL programs.

Not too many folks fiddle with EPROMS anymore. Microcontrollers with onboard EEPROM are cheaper and easier to program, plus you get some logic that allows you to reduce the circuit complexity thrown in for the ride. Of course, these things grow ... with the logic, an encoder is cheaper and more pleasant to use than the thumbwheel, but now you would like to add a display .... and on and on. But still, I wouldn't be surprised if the micro, encoder and display wasn't still cheaper than the EEPROM and BCD switch.

Error!  There are plenty of people using eproms for systems and other
uses.   I keep a programmer for such a reason.

A micro like a PIC would likely be a lower cost solution and you can
then uses a cheaper switch and all.   A programmer <really more of a
cable> for a  PIC can be easily built for a PC parallel port.

with my computer, however, I'm not that good at programming a PIC either! There's
a control head that comes with this rig, that allows me to select twenty
frequencies, along with power, squelch, and other things. I can probably get a
board to use the PIC with, however, I know absolutely nothing about PIC
programming! Last time I used BASIC was back in the early eighties! There as a
project some time ago called the "Kendra Board" I believe in either 73, or CQ,
using a PIC.

I am 100% disabled. I can not get a job, so I don't have to worry about a security clearance.

> Your credit rating matters.

In most cases, but not always.

> And I also note that many of those who are bad credit risks deal in
> cash only...because it is the only way others will deal with them.

I got in the habit of paying in cash about 35 years ago when I owned a business, and my suppliers gave a 1.5% discount for paying cash within 10 days of the monthly statement being mailed. I paid cash for vehicles whenever possible to save the finance charges. In 54 years I have financed one new truck, and one home, 30 years ago. I have no need for credit, because if I can't afford something, I'll do without it. The VA takes care of all of my medical needs, and everything else is paid for. I'm getting old and with my health problems I have no idea how long I'll be around. Its not the big deal it was when I was 20 years old.

Oh I read the requirements. I meant that I didn't agree with them, and
I wrote an email to ARRL with that opinion. They replied back to me
with your analysis, that they wanted a solution that would be applicable
to most computer users, but they also liked the idea of a multi-platform
project. Maybe they might open up a category for Linux.

The advantage of Linux is that the development tools are free, and Linux
will run on any computer that runs windows. You can also install Linux
on top of windows (on the same computer anyway) and dual boot, so you
can have your cake and eat it too (or have your poison and antidote too
in my opinion!).

I applied for a credit card in 1972 and was turned down because I was an E2 in the US Army. You had to be an E6 with five years to qualify, so I decided I was never going to waste my time applying again. The credit card companies have probably spent more trying to get me to apply for a card since them, than I would have used that Chevron card for.

I really can't travel very far, so I have no need to rent a car. In fact, my truck was out of commission for over a week before I was able to crawl under it and cut the damaged exhaust system apart and fix it. I asked the young man who volunteers for the "Computers for Disabled Veterans" project get me a few groceries, but otherwise I didn't miss the truck. He is learning computer repair, in exchange for helping me finish more computers.

I have always lead a simple lifestyle. Sure there are lots of things around, but I rarely buy anything new. Only when I can't fix something, or build it from what I can find. Its very satisfying to look at something you've built and have someone ask, Wow! Where did you buy that? :)

I have picked up a couple truckloads of free angle iron bed frames to build some work carts, but first, I have to build a welding table. I have a lead on free reject sheets of plywood from a local mill to make shelving out of. Any sheet that has a splice, or is missing any glue is rejected. I want to build some shelving to store the spare computer parts, and wood trays to hold Hard drives, CDROM drives and Floppy drives. That way they can be sorted, tested, and ready to drop into a computer, as needed.

BTW, I was given another Compaq like yours with the VGA connector sheared off the motherboard. It works with a replacement AGP card, but you know me. I'm going to replace the connector so I can see if the onboard video is still ok. ;-)

   The crap on news:sci.electronics.misc is crossposted from
news:sci.electronics.policy, which is a watering hole for the biggest
idiots on usenet.

Does anyone have experience with this portable Morse training device, or others like it?

It's depicted here:
http://home.austin.rr.com/jfisher2/MCD.htm
K5JHF told me that no inventory remains and he does not plan to make any more. I am curious about how useful it proved to be for gaining and improving Morse proficiency.

Portability seems like an advantage, enabling the device to be used while driving, exercising, etc.

Tom, N3IJ

All,

One of my neighbors in the principal of a middle school that is interested in incorporating amateur radio as part of it's science club.
   This is located near the Navajo reservation.
I'd like to train the members to be Tech+ and focus on the Novice CW bands, because for these kids brass pounding across the country is where the 'wow' factor is.

Anyone interested in donating books, equipment, or junk boxes? It would be tax deductable.

Thanks in advance,

The Eternal Squire

Hello all of you,
  I am using my MFJ-269 now more frequently.
  The more I use it the more I have questions.
  What kind of connection do you use when you want to measure inductor or capacitor or to check the impedance of a resistor ?
  I have use the cable of my scope and a homebrew pl259 with wire and aligator grip with various result.

Happy day

Hi Jean, I use a PL259 and a couple of short pig tails (6cm) with an minature alligator clip.

If you are measuring L or C, their Reactance is frequency dependent. The frequency at which you measure must be such that Xl or Xc is less than 650 ohms. (the MFJ takes the reactance and the frequency and converts that to L or C).   Sometimes the frequency will be high enough that the stray L or C of the pig tails will affect your reading. Up above 20-25 Mhz I measure the L and C without the component hooked up and subtract that reading from the one I get with the component connected. Hopefully that takes some of the error introduced by the long leads out.

Gary N4AST

You can check out my free program:
http://www.xertech.net/Projects/CPwin.html

or scroll down the page to a set of zipped pre-recorded mp3 files.

I wrote it so I could record sessions and practice with a cheap personal
audio player. Key feature is audio voice prompt of what was sent in cw.
I think the idea works, but I need to keep at it myself. I never seem to
keep at it long enough to improve.

+++++++++++++++++++++++++++++++++++++++
Rex , Thanks for making this prog. freely available , it works very
well.  Congrats.
The large character display  & voice feedback is excellent for visually
impaired users.

I have passed the prog on to other hams.

And, it appears not to comply with several specific FCC regulations:

-  It has gain through the CB frequencies (violates 97.317 (b)) and is
   thus not eligible for certification, which is required for amps
   operating below 144 MHz.  The FCC may be about to relax or eliminate
   the 97.317 rules about external amps operating in this frequency
   range, but for the moment this reg is still part of the law.

-  Its second- and third-harmonic distortion levels are roughly
   10 dB too high to meet the -43 dBc requirement (violates 97.307
   (d)).

Hi..
In the past, I've always mounted my coils vertically but
this time around, I need to mount some horizontally.  I was
simply going to glue them to the pcb but wanted first to get
input as to other home brewer's method of mounting toroids to
a pcb.  The toroids will be FT-37-43 type wide band transformers
in the 10MHz range. Your input is welcome.  Take care.

Perhaps it's designed for IPods? Most everything seems to be!

Hi Jim, I guess the first thing I would consider is differences with
the leads getting to pads. Horizontal is more stable than vertical,
but takes up more space. I guess the big factor would be the space
requirement. I would never mount one vertical if there were space for
horizontal. That determination would be dependent on the layout of
your circuit board. Good luck.

Yeah. A touch of silicon adhesive or hot melt seems obvious. Can't think
what more is needed unless you find something that seems to not be
working as expected.

Does anyone have or can they direct me to a couple of "splined" tuning shaft adapters that fit the ARC-5 Command Set receivers? I'd like to adapt some of the ganged variable capacitors from those sets into some homebuilt equipment...lovely antibacklash gear reduction on them.

Been trying to search the 'web (at the usual suspects such as Fair Radio, Toronto Sales, etc.) but no joy. Yes, I know that some consumer radio plastic knobs will fit, but those also break very easy making the MTBFs very low indeed.

I would suppose that there is a mechanical description for the splines and diameters but, alas, I ain't one of those. I've a feeling that several mechanical hardware suppliers have them in stock.

Will appreciate any info, will trade assorted items for a couple of metal adapters to metal shafts.

Place a thick plastic washer between the toroid and the board to reduce
stray magnetic and capacitive coupling between coil and metallic surface.
Toroid coils are not completely devoid of coupling to nearby external
objects and surfaces.
```

I've always mounted smaller toroids (<1" OD with copper) vertically. For larger ones, either a pair of cable ties of some neutral cure silicone adhesive works for me.

Hmm... that doesn't really seem that much easier than just using a glue gun in
the first place, is it?

Personally I'd also worry about detuning due to having the coil sitting right
on top of the ground plane like that, but I suppose that if he's manually
aligning everything anyway it doesn't really matter.

Tom,
One other odditiy I found after replying was that with the 10dB basic pad loaded in in RFSim99, giving the bogus S parameter, by clicking on the up or down arrow for tolerance in the simulation mode, it would give what appeared to be reasonable results. However, clicking on the button to return it to normal gave the bogus value again. I guess I was optimistically thinking that after the tolerance iterations, it would see the error of its ways and give a realist value. Obviously, the software is not "self-healing", ala the topic of the recent IEEE Spectrum article.

What you say about extreme sensitivity is on the mark. I later experimented with GPLA and saw the same effect. I hadn't thought of it in the balanced bridge context.

The main reason I haven't homebrewed one of Rick Campbell's IQ designs is the need for those tight parameters, which translates to relatively high cost in the parts required... :(Some of the inductors for one of them, the IQ DC receiver, I think, are no longer available when I checked Mouser and Digi-Key. I suppose AADE still has the stock, but building from scratch is obviously cheaper if you can get a direct source.

One femtoFarad? Wow! I'll have to play around with this some more, and your idea of paralleling (or series-ing, I guess, as well), sounds interesting. It could be an indicator that the results are valid, I should hope.

I really like RFSim99 as a first-cut design tool. Very simple and straightforward. It's very nice for L-networks. As with the AADE filter designer, I typically then run any design through at least one other tool for confirmation. I've had some problems on occasion with crystal filter design for certain configurations using XLAD, so I've done the design using another tool, such as the AADE design tool, and then entered the values in LadBuild, and continued to tweak in GPLA.

We're very fortunate to have such programs at our disposal.

Mike,
Tell us how you *really* feel! ;-) .

I didn't see any BNC bulkhead connectors, which is what I typically
use for price comparisons, since I seem to use so many of them.  I
haven't ordered from this vendor, but I'm tired of having the
insulator melt on some of the ones I've bought for about a buck.

Hmmm...not a bad idea.  I have no use for a Miracle Whip antenna, but
I think I'll try that approach as another alternative to Phil Salas,
AD5X's portable vertical base matching techniques.  It might even be
feasible for the tuneable component of a center loading coil.  I'm
gonna do some experimentin'!

Direct conversion is used in nearly all modern mobile phones, because it is cheaper (no IF filters), and because the baseband amplifiers use less current than the old IF amplifiers used to. The RF performance is not necessarily as good as a well designed superhet.

It is difficult to make the receiver immune to "AM detection" which is a problem caused by receiving a strong interfering signal with amplitude modulation on it, at a frequency other than the one that you are trying to receive, but which somehow gets turned into a baseband frequency signal coming out of the mixer, even though it shouldn't. There are plenty of reasons why this can happen, such as second-order nonlinearity in the mixer, meaning that a strong interferer coming into the RF port of the receiver can mix with itself in your mixer and end up on top of the wanted signal. Another cause could be if there is coupling between the LO generation circuit and the RF input (in either direction, both are bad.)

Also it is common to get large DC offsets coming out of direct conversion receivers, and for some modulation formats where you're interested in frequencies down to DC, that can be a pain. People have pretty much solved these problems in phones, after a lot of work.

Chris

Hi Len,
nope - rare as rocking horse manure. I machined ones from brass rod -
receiver end, a press fit on the splines, other end, quarter inch for
knob.

Andrew VK3BFA.

Guys..
Does anyone have any better method for stripping small, enameled wire, other than using sandpaper or an exacto knife (scrapping)? There used to be a chemical stripper called 'Xvar', years ago. This stuff worked great. Nasty stuff as you can imagine and has been EPA'd years ago. Is there anything comparable, today?

Also, a retired technician that I once knew had a pair of ingenious 'stripper pliers' that he had acquired back in the '60s that did a fabulous job. These pliers had special jaws that would scrape the enamel off without nicking the wire. They worked GREAT. Supposedly, this tool originated from a mfg in Germany. I have never seen this tool since. Anyone have a lead on something similar?

Thanks and take care.

I've heard about that tool, also.  My only experience with enameled wire
is melting/burning it off, then sanding off the little remaining crud.

I know, probably "Been there, Done that".

For a long time, I've used heat-strippable wire which I got surplus. It can be stripped just by heating at 750-800 degrees for a minute or so with a soldering iron. The trade name, I believe, is "Solder-eze", but a web search doesn't reveal a ready source. (I did find a number of people asking where it could be found, but no responses.) Hopefully a reader knows of a source and can tell us. A nice summary of various ways to strip heat-strippable wire is at http://www.ac6rm.net/mailarchive/html/elecraft-list/2005-10/msg00598.html.

While searching for information on heat-strippable wire, I came across the suggestion for stripping conventional enameled wire with paint stripper. Apparently it takes a few minutes, but does work. It's nasty stuff to work with, though.

Thanks, Andrew...I got that impression after several hours of web
surfing. :-)   :-(

My 1948-acquired Command Set surplus stock has slowly
withered away ($6 for receivers, $12 for transmitters, $18 for

antenna tuning unit-modulator-Tx dynamotor at that time).
I'd gotten 4 of the tuning "knob" adapters back then, 2 got
traded-sold, 1 remains on a 6-9 MHz receiver, and 1 is lost
somewhere unknown.

Beautiful anti-backlash worm drive on those ganged capacitors.
Would be good for tuning anything.

Not being a machinist I was hoping someone would come up
with the correct words to describe the splined whatsis so that
I could haunt a few mechanical parts suppliers for something
that would mate smoothly with it. I tried some copper tubing
(pressed over splines) with marginal success (several
diameters, easy to get at do-it-yourself stores for various
small water piping uses) but those bend rather easily. [it's not
too swift when one's home machine shop consists of a Big Lots
table top drill press...:-)]

I did come across a Magnificent website with Great pictures of
WW2 radio equipment in US military aviation: http://aafradio.org
Now there is a Collector! [and a consultant at the Smithsonian
Air and Space Museum]

I mentioned a commercial paint-stripper in here, have tried another brand. Wayyyy slow. Having used commercial paint strippers in days before EPA had declared nearly everything "toxic, harmful to health" those paint stripper compounds were a lot stronger. It works, sort of, but one can use up a half roll of paper towels to make a dozen-plus toroid inductors' end-stripping. [okay, some exaggeration there]   It is messy and usually takes a second application of goo to clean it off good enough for soldering.

GONE is good old General Cement "Strip-X" (company says it has no plans for anything similar in future) and the "Solder-Eze" is relegated to "old stock." Since "magnet wire" is still used in industry, hobbyists need a hint or three from those working in that area now.

With FT-37-43 toroidal cores, the outer diameter of the form
is 3/8 inch, right?

There should be very little change in inductance by simply
gluing that small an inductor to a non-conductive spacer
at least 1/8 inch thick...such as most any plastic material.
I've used two-part epoxy from the hardware store, a silicone
RTV goopy stuff (from same store), even my wife's glue
gun for craft work (lots of TLC involved in such persuasion),
all worked well. I'd judge that the two-part epoxy would be
the most long-lasting on fiberglass-epoxy substrate boards.

It would be fairly difficult to do it on it's own. Using a pocket PC or
some similar device, you could do it easily. The problem is finding a
device that could do it that would not cost more than the HT.

Basicly what you need is some sort of system that accepts connections
from bluetooth devices and plays the digital sound to a digital to
analog converter. Since a pocket PC has the bluetooth and a "sound card",

it would be simple under Linux. It might be simple under WINCE, but
I only know about building handheld Linux devices.

Geoff.

Depending on your location you _might_ still be able to buy a quantity
of MEK (methyl ethyl ketone) at a paint or hardware store. This is a
strong and effective stripper for many insulations, and may very well
have been the primary ingredient in the Xvar stripper you mention. As
you say, it's bog-nasty stuff, and should be used with serious caution.

Some people just flame the end of the wire briefly - long enough to
scorch the insulation but not long enough to oxidize the wire. It
makes scraping off the insulation much easier... but takes practice.

Not marketed as such, but there *are* Bluetooth adapters out there for devices that use "standard" headphones and microphones, such as cell phones (e.g., http://www.amazon.com/Jabra-A210-Bluetooth-Adapter-2-5-Universal-Headset-Jack/dp/B0006HES2I/sr=8-1/qid=1158779198).
Adapting that to an HT is, I expect, no more than perhaps a bit of level matching an connectorization.

Another variety of this is Belden "Beldsol", which seems to be widely
available... Mouser, Newark, RS Electronics list it.

And, an eBay search on "solderable magnet wire" will probably turn up
some supplies of this sort of wire.

I've purchased some from RoadRunner in the past:
http://www.rrunner.co.uk/wire/qse.htm ... probably not particularly
cost-effective, being overseas, but if you only need small quantities it's OK.
Another UK company, Vero, has it as well:
http://www.verotl.com/products/index.cfm?content_id=7846BCBE-F067-441A-9F53A51D8E4CC6B3 -
- never dealth with them personally.

============================
Not knowing the equipment being discussed ,I could suggest the following general method of extending a 6 -6.35 mm shaft . (6.35mm equals 1/4 inch)

Take 2 (if possible identical) non metallic knobs for the shaft diameter concerned ,for example the push-on potmeter knobs found on almost any VDU or older TV and BC radio sets , used to push onto splined potmeters . Equipment from Asian origin is always metric ,hence shafts dias are 6 mm . Fit the 2 knobs concentrically piggy back ,with either epoxy or 2 or 3 bolts /nuts either metallic or non-metallic (say nylon).

Push/fix 1 knob onto the splined shaft to be extended.
Fit tubular/solid extension shaft into other side.

If alignment with front panel opening is a problem , glue flexible material (for example rubber ,dense foam or expanded polystyrene)in between the 2 knobs . Of course all this provided there is enough space in the enclosure.

This method is also very suitable for applications involving components with a rotary shaft which should be kept free from ground ,like in antenna matching units (tuners) .

If the to be driven shaft has a 1/4 inch diameter the mating knob must suit this ,but the other knob can be for a 6mm dia shaft and final front panel knob There is a lot of flexibility.

Len, today is your lucky day. I have ONE splined whatsis, the tuning knob
that was included in every maintenance kit for the BCxxx series. Steel with
a heavily knurled 1/2 inch knob.

Send me your snail mail address, pretty sure I'm not going to be using it.

Only if the HT has a VOX function.

Geoff.

> I mentioned a commercial paint-stripper in here, have tried another brand. Wayyyy slow. Having used commercial paint strippers in days before EPA had declared nearly everything "toxic, harmful to health" those paint stripper compounds were a lot stronger. It works, sort of, but one can use up a half roll of paper towels to make a dozen-plus toroid inductors' end-stripping. [okay, some exaggeration there] It is messy and usually takes a second application of goo to clean it off good enough for soldering.
>
> GONE is good old General Cement "Strip-X" (company says it has no plans for anything similar in future) and the "Solder-Eze" is relegated to "old stock." Since "magnet wire" is still used in industry, hobbyists need a hint or three from those working in that area now.
>
> LenAnderson@ieee.org

Years ago, working with "Litz wire", I used Red Spirit and a small burner or a small blow torch. We dipped the wire in the spirit and then burned it.

I'm not entirely sure if the Litz wires we used had secondary lacquer isolation but I think so and that was the major pain with that wire.

A quick heating up and a swipe with a cloth should do it. Red Spirit was originally almost clean Ethanol (While doing my military service in the Signal Corps ages ago, we used to nick it and mix it with coke or tonic water on Friday evenings...)

Cheers

You can buy a cheap BT adapter for a couple of Dollars. You also need to add
a simple VOX to be really happy. However!!! I do recommend you getting
one of these throat/vibration mic headsets with a thing plastic tupe as
earpiece. Replace the original BT mic+earpiece and you have a solution that
actually works.
BT headsets are notoriously bad as they pick up to much noise. A throat mic
is just so much better. Also, these throatmic headsrets comes with a neat
ptt on a vcable. Vox just doesmn't work properly on a bike unless you have
it low sensitivity and really shout at it for tx...

Cheers

I started to respond to your "FAQ" and then changed my mind, but your persistence compels me to respond. I too have been using the 'net for a considerable time, and FidoNet before that.

Thirty-some odd years ago I became interested in becoming a "ham". Several years earlier I had built my first receiver and became interested in electricity at an age when most kids are still trying to get their heads around "See Spot run."

I met an old ham who gave me stacks of "CQ" magazine and ARRL handbooks, most of which I read cover to cover. But, things change and I didn't get my ticket. Eventually I wound up in the Army, working on radar systems (among other things). I am technically inclined and currently work with computer hardware.

I never lost interest in radio and have always been involved, one way or another. Over the last few years I again entertained thoughts about getting my ticket. But, things seem to have changed...and not necessarilly for the better.

It seems to me that qualifications have been relaxed. Is this an attempt to increase participation in an area with declining interest? I don't know. But I do know a few current hams, and I started reading the rec.radio.amateur.homebrew newsgroup, going back to Dec. of 2005.

I am sure that there are still many helpful hams who are good people to know, I've read a number of them in this particular group. Unfortunately, there seems to also be an increasing number of people whose attitudes are repellant...including yours.

You rant about "childish insults", and immediately proceed to insult others in the same manner. You have *your* opinion of what "ham radio" is (or ought to be), and you announce that you are going to jam it down everyone's throats whether they like it or not. Frankly, I really don't see a whole lot of difference between your behaviour and that of some of those dislikeable individuals on the 11 meter band (which you denigrate as a whole with your repeated remarks about "Childish Broadcasters"). In fact, your insistence that your "FAQ" "will not be shouted down" reminds me very much of the individuals who lock down the key and proclaim "Nobody is going to talk over me" and proceed to repeat a bunch of gibberish which serves only to restrict and interfere with civilized conversation.

Though I tend not to participate in the nonsense which occurs in the "normal" portion of 11 meters there are some good people there, as there are in other areas of the spectrum and with whom I communicate. And, despite your assertion to the contrary, there are many of us in and outside of 11 meters who are interested in how radios work, and who build/modify and operate our own equipment.

You also assert that "A Ham Radio licence is such a desirable thing to have...". If it is so "desireable", then why are the standards being relaxed so as to lower the barrier to entry? In your own "FAQ" you you say that the standards are now "trivial" and "set for six-year-olds". What other reason for this could there be besides a declining level of interest?

>they are free with rather silly personal insults.

Pot? Kettle? Black?

> One infallible way to disambiguate the CB Radio Hobbyist from the _REAL_
> Radio Ham is to solicit their view of the difference between CB Radio
> and Ham Radio. A Radio Ham will perceive Ham Radio to be a technical
> pursuit and will perceive CB Radio to be a social communications
> facility

What makes you think that *your* opinion is the only valid opinion? Or, indeed, that it is valid at all?

Strictly a technical pursuit? Surely you jest. Even in the past when technical knowledge and code skills were of greater importance, even "ham" radio was a "social communications facility". The fact that much of the communication may have been technical in nature in no way lessens the "social communication" aspect.

> There is not today, nor has there ever been, a need to go out
> and encourage and press children, children who have never expressed an
> interest in Ham Radio, to come into our shacks. Such an activity should
> cause eyebrows to be raised - what normal well-adjusted adults seek the
> social acquaintance of children?!

What? I'm not even sure how to respond to *this*, except to say that were it not for adults introducing me to various technical pursuits and encouraging me to get involved, and teaching me, I would not have accomplished a fraction of the things I have done over the years.

> Please remember that this FAQ is a _POSITIVE EXHORTATION_ to you to
> exert yourselves to join our fraternity!

If that is your intent, I think you are falling far short of the mark. In fact, you have reduced my interest in obtaining an amateur license practically to zero. Was it Groucho Marx that said "I wouldn't be a member of any club that would have me"? I think I'll take a "pass" on joining *your* "fraternity". You've even got me to thinking that maybe the government(s) should stop wasting money on regulating the amateur bands, open them up to anyone who cares to operate on them, without restrictions, and abandon them them, much as they have done with the "CB" band in the US.

I'll continue to operate my radios but I see little point in expending the effort to get a ham ticket just to encounter the same sort of people that I can run into on 11 meters with no effort at all.

Say, how are you doing with that question of which end of a resistor is

```
which? When you get that worked out, perhaps you'd care to comment on the
feasibility of using a tuneable Klystron oscillator to drive a magnetron
in a high-power pulsed RF application.

Certainly worth checking out, but I'd be surprised if most people felt that
KiCad and EAGLE with "roughly comparable" -- most people would definitely tend
to prefer one over the other.

not really, only G8DXY would have access to the Ref number on Beanies Validation Document.

Positive can/case is standard alkaline cell construction. The correct
question would be "has anyone ever seen a negative cased alkaline cell?"

Thanks for responding Glenn!

> Provided you implement the Tayloe mixer with sufficient baseband
```

> bandwidth (probably about 20 KHz for NBFM), you can mix, say, a 2 meter FM signal to baseband and demodulate it with an audio discriminator (some sort of audio frequency to voltage conversion scheme). Mix the signal to be either exclusively in the upper or lower sideband of the output. So, for example, a NBFM sig at 146.000 MHz mix with the Tayloe mixer set to 145.990 MHz and select the upper sideband. The upper or lower sidebands are, as you probably know, selected by phase shifting and summing circuits following the Tayloe mixer (implemented in software in SDRs). Note that SDRs like the Flex-Radio SDR 1000 do not process incoming signals near 0 Hz anyway, but mix the desired signal centered around about 11 KHz (I think).

So the phase shifter is NOT for flatten the group delay variance (source is the Tayloe mixer low-pass)?

Is multiplying I with Q enougth to demodulate FM as in a quadrature demodulator?
I cannot find a suitable theory page to look for.

>
> The Tayloe mixer is a passive mixer terminated in large capacitors, and similar performance can be obtained at VHF, UHF and microwaves with two FET ring mixers driven with quadrature signals and also terminated with capacitors (that is, no wideband transformer on the mixer outputs, but capacitors followed by HiZ input differential audio amps). I've done this with the Peregrine Semiconductor FET mixers.

Thank you for given the link to Peregrine. I read the datasheet. How do you mix it?
At the moment I prefer the Tayloe mixer because of it's simplicity.
BTW: They have a nice low-power consumption PLL being compatible to National.

At TI I found nice tinylogic capable of switching like a 4066 down to 500ps ...
Should be possible to run the mixer at 150MHz with it.

> Only familiar with the dsPIC, though the others sound okay. The dsPIC would work, though its 12 bit A/D doesn't give a lot of dynamic range. Plenty for NBFM though, especially since you can run the signal(s) through a limiter first. For NBFM sixteen bit DSP is sufficient.

How much dynamic range do I need? I thought about 100dB?
If I recall theory I loss 2dB if limiting the signal to remove AM sensitivy.

regards -
Henry

Henry Kiefer wrote:

> So the phase shifter is NOT for flatten the group delay variance (source is the Tayloe mixer low-pass)?

If I understand your question correctly, that is true. The IQ output from the Tayloe mixer (or any IQ mixer) is not upper and lower sideband. To get those you must do further signal processing, which usually involves shifting the I and Q channels ninety degress with respect to each other then summing or subtracting the channels depending on which sideband you want.

> Is multiplying I with Q enougth to demodulate FM as in a quadrature demodulator?
> I cannot find a suitable theory page to look for.

I can't either. The IQ signals multiplied do not make an FM quadrature detector as the phase does not really shift much over the NBFM bandwidth. There may be a clever way to extract FM more direcly from the IQ channels without first detecting a sideband, but I don't know it.

> Thank you for given the link to Peregrine. I read the datasheet. How do you mix it?

Maybe the wrong part? I'm talking about the PE4140 FET ring mixer. You use two, driven with LOs ninety degress out of phase with respect to each other.

> At the moment I prefer the Tayloe mixer because of it's simplicity.
> BTW: They have a nice low-power consumption PLL being compatible to National.
>
> At TI I found nice tinylogic capable of switching like a 4066 down to 500ps ...
> Should be possible to run the mixer at 150MHz with it.

Yeah--digital just keeps getting better. Good luck.

> How much dynamic range do I need? I thought about 100dB?
> If I recall theory I loss 2dB if limiting the signal to remove AM

sensitivy.techniques,

You need good dynamic range up to the limiter. This can be done with analog circuits as discussed. After the limiter an A/D converter is not even needed in theory--a fast-running timer hooked to a digital port could do the trick. I don't remember any loss by removing AM in the limiter (since all the the information is contained in the

```
frequency of the signal), but my theory is in the distant past, back
when FM meant 'funny math'.

Regards,
Glenn

I thought all of the carbon/zinc type batteries had negative cases. The little button on the top is the positive contact for the battery and the other end is essentially flat on most batteries today with some having a stamped bottom and sides in contact.

FM the problem is not responding to amplitude changes but frequency
changes. So any system that can count and measure frequency and
render a pattern based on changing frequency.

Synthetic PLL or simple a software PLL. would do it.
The synthethetic PLL approach means a software oscillator locked
to a varying frequency external signal. The error word generated is
the demodulated signal (apply to D/A or use raw).

>> How much dynamic range do I need? I thought about 100dB?
>> If I recall theory I loss 2dB if limiting the signal to remove AM
sensitivy.techniques,

Dynamic range is one of those the more the better but, many things
like noise eat away at it. These days a radio with >80db is good
and >90DB excellent, 100 Db is attainable.

>You need good dynamic range up to the limiter.

You need good dynamic range up to the first selectivity that can
remove offending close in signals.

Then you can limit hard. If you limit before or without adaquate
selectivity you will have intermodulation problems.

> This can be done with
>analog circuits as discussed. After the limiter an A/D converter is

If the signal is limited then zero crossings are enough. That could
be expressed as 1bit.   Your now working in the time/frequency
domain.

Allison

Should work just fine. I haven't done it, but I do have a 4-400 and am thinking about just what you propose.

See:

That's simple. One end is the goesinto while the other is the goesouttta unless you hook it up backwards. Then due to great foresight from the engineers the two ends will automatically swap functions making the device appear to be bidirectional.

>>
>> Or a multitude of other reasons why people become radio amateurs given

Some of us use it for exercise:
http://www.rogerhalstead.com/ham_files/Tower29.htm

Or the whole project http://www.rogerhalstead.com/ham_files/tower.htm

Although I've been known to use the exercise excuse so I can put up more antennas. Unfortunatley I have to get the 144 and 440 arrays down. I already have the mast down to about the 6-meter yagi and have rebuilt the PST-61 rotator.
>
>Good advice Steve. There are even people who buy s/h homebrew equipment (eg
>a QRP radio) at rallies and probably take great delight in using it.

Lets see... My first home brew rig was about 90 Watts with a pair of 6L6s and a 6AG7 oscillator. Not exactly QRP. The next home brew projct was a 6C21 HF amp (those things are big) and then a pair of

813s. on HF. Both home brew but a long way from QRP with the exception of the time when I blew the plate out of a 6C21 and it turned into a dummy load. I wish I still had that thing if for nothing more than a conversation piece.

OTOH there is a fair amount of HF QRP around this area (Central Michigan) with some of the rigs getting fairly sophisticated.

There is a lot of developmet work going on in digital here. The local system can broadcast the latest RADAR to the laptops of those of us out storm chasing. APRS (if set up in the car) gives your coordinates back to the EOC. They are working on a portable TV Repeater for a number of reasons in addition to being used for damage assesment.

There's also the networking of packet, repeaters, and the internet.

We have ham stations in both the EOC and the mobile EOC unit. There was talk of adding HF ham stations to both locations.

I've not seen a 4-400 amp on six,, but they are rated to 110 MHz and the book shows just shy of the legal limit out at 75 MHz.

I don't know how difficult the'd be to neutralize.
Sounds like fun and I think they'd be a better tube for six than
3-400s or 3-500s.

Good luck,

According to Bob May <bobmay@nethere.com>:
> I thought all of the carbon/zinc type batteries had negative cases.

Most did -- but the zinc/carbon individual cells are relatively rare now. An example of the zinc-carbon ones without a negative case are the ones which were used to make high voltage batteries (even the 9V ones) were a wax ring (shaped sort of like a tire) with a zinc plate at one end and carbon at the other, with the sal-ammoniac (IIRC) in between. All of the wax rings were joined end to end by melting the wax, and this connected all the cells in series.

> The
> little button on the top is the positive contact for the battery and the
> other end is essentially flat on most batteries today with some having a
> stamped bottom and sides in contact.

The "little button on the top" was a metal cap over the end of the central carbon rod which was the actual positive terminal.

However, the Alkaline cells use a different chemistry (I'm not sure of the details -- but it could be looked up), and the positive terminal makes the case -- which requires a strange form factor to deal with all the equipment designed to orient the button properly as a positive terminal. A standard flashlight would not care, but most electronic stuff powered by batteries does care, which is why they continue to shape things so the button is positive, even if it is connected to the case. The common coin cells are different, because there were never any of those with the button as positive.

Enjoy,
DoN.

=====================================

Up to the mid 1970s type 4-400 transmitting valves (tubes) were used in the UK in Band 1 (approx 45-65 MHz)TV transmitters.
For a 7 kWatts area transmitter there were 7 chassis of 2 valves each.
So they should be excellent for the 50 MHz amateur band.

A very early design can be found in QST March 1967 ,pages 11 - 15.
Titled : Six-Meter Kilowatt with 4-400As or4-125As.

The design involves 2 valves (tubes) in push-pull config.

Although push pull RF Power Amps are nowadays no longer or not frequently used , I feel it is still interesting reading and might give some ideas for a homebrew amplifier.

If you can't find the article , I can send you a scanned copy of the 5 pages.

To email me remove the obvious chars from the above address.

Frank   GM0CSZ / KN6WH

That site would be more convincing if it wasn't a come-on to use THEIR version
of "Paypal." Paypal is OK, IF you use common sense.

Please see www.aaarfproducts.com

Here's some information from Cox Communications you should be interested in, shortly:

"Newsgroups. Messages posted to newsgroups must comply with the written charters or FAQs for those newsgroups. Advertisements, solicitations, or other commercial messages should be posted only in those newsgroups whose charters or FAQs explicitly permit them. You are responsible for determining the policies of a given newsgroup before posting to it. Posting or cross-posting the same or substantially similar messages to more than eight newsgroups is prohibited. Our news software will automatically cancel any messages posted to nine or more newsgroups.

Binary files may not be posted to newsgroups not specifically named for that purpose. Users posting binary files to groups with policies concerning the permissible daily volume of posted files are required to observe those limitations.

You may not attempt to "flood" or disrupt Usenet newsgroups. Disruption is defined as posting a large number of messages to a newsgroup, which contain no substantive content, to the extent that normal discussion in the group is significantly hindered. Examples of disruptive activities include, but are not limited to, posting multiple messages with no text in the body, or posting many follow-ups to messages with no new text. Messages may not be canceled, except by the author or by official newsgroup moderators performing their duties. "

This is from their AUP on:
http://www.cox.com/policy/#Acceptable_Use_Policy

You'll find none of the newsgroups you spammed with this post allow commercial spam in their FAQs.....

Cox has our reports....This ISN'T your free advertising medium....

Your IP is easy to find:

Never had a problem with Paypal. Ever. In fact, I generally don't bid on auctions UNLESS the seller takes Paypal.

Is it just a coincidence that this collection of horror stories is selling an alternative?

Because of phishing, trojans, and other very smart crooks trying to get
into my account, and also because of Paypal complaints that are legion,
there is no way I would link up my main bank account with Paypal. When
I sell something on ebay, I request payment by a money order, when I
buy something on ebay I pay by money order. If the seller wants Paypal
only, I move on to the next listing. I have noticed that more and more
sellers are glad to accept money orders, especially individuals who are

selling their own stuff. I have had no problems with Paypal but there are just too many really clever scammers working the internet. I maintain a tiny account in a different bank to handle fees: if I do get hit by a crook, or by Paypal, the loot would only be about $5.00. In addition, in Canada, interbank money transfers are safe and inexpensive.

One compelling reason to ONLY fund PayPal with a Credit Card that
will charge-back unauthorized activity and to request a check if you
have more than $20 in your account.
They cannot take what they don't have.

RS

Many years ago, there was an article in QST (I think) that used a pair
of 6C21 radar pulse modulators in Push pull with copper pipe for a
tank circuit. I don't remember what they used for a link but I think
it was just a u-shaped piece of smaller tubing.

That thing would put out today's legal limit with a sneeze. Even more
if you turned the driver on.

Unfortunately 6C21s are big (bout 16" tall), difficult to find, and
expensive. I used to pay $5 USD each.

Doug:

It was the wide use of these tubes (along with others like the 4-250 and 4-1000) in the TV and FM broadcasting industry that made them so plentiful and allowed "used pulls" to be so readily available to hams. Amp designs using them have been around for decades. I just looked in the 1965 ARRL handbook and they have a 4-250 amp for 6 meters. A little homework should turn up many more.

Good luck,

Roger K6XQ

Stolen from http://makezine.com/blog/

http://www.makezine.com/blog/archive/2006/08/carl_jerry_adventure_in_electr.html

Carl & Jerry were way before my time, but one summer vacation I ran out of science books in our library's children section. So I got permission to start reading all the back issues of Pop Electronics on microfilm. Found lots of cool stuff from back before I was born!

Aarrgg! This is very disappointing! I usually check at least my values for LC circuits against the LADPAC programs In "Experimental Methods in RF Design", however. By the way, when I click on Tools/DesignAttenuator, the schematic that is in the pop-up window for default 10 dB shows the three resistor values as 71.151 and 96.248. When I go through the process you did, I get the same results. I saved the file, and closed and reopened the program. Then, I loaded the saved 10dBAtten.cct file, and of course got the same -102.69 dB for S11. Then, I Tuned the values back to 71.151 (which immediately displayed only 71.15), and tuned the other two to 96.248, (which displayed 96.25). When I simulated, S11 was now -107 dB!

I just ran the simulation in the LADPAC programs. I first built the attenuator in Ladbuild, with the resistors rounded off to two decimal places, and saved the result. In GPLA, I got (after resetting the scale to -120 dB) S11= -107.3. Then I edited the values to the 3 decimal place values from the original attenuator pop-up window of RFSim99, and got S11=-121.67.

The circuit review feature of GPLA still showed 2 decimal places, rounded off, but saving that version of the attenuator and opening the saved program in Ladbuild showed three decimal place values when clicking on the component.

It's surprising how a couple of thousandths of an ohm can change the S parameters that much.

Ted KX4OM

Dewd! I recognized the title of this one:
http://home.gwi.net/~jdebell/pe/cj/v18-3.htm
"Succoring a Soroban", and within two sentences I split a gut.

They probably wouldn't be allowed to publish such politically incorrect
stuff these days. ;-)

Cheers!
Rich

I'd give a lot to get a copy of a PE article that ran in the (I believe) 58-60 time period regarding a "Game of 21" that was played with a telephone stepping relay, where it was "you against the computer". I'd like to do a discrete digital version for my freshman students as a lab project.

Designing the logic is simple; giving out a copy of "how we did it in the '50s" is priceless.

Its a great site if you want no name connectors and coax so bad that radio shack would be ashamed to sell it. I see that he no longer posts his e-mail address in his spam. He's a foul mouthed pain in the ass.

Your righteous indignation would probably have worked better if you
had provided a valid URL.

-Chuck

You are correct. That's what happens when one gets freally p*ssed off! The URL should be:

http://w2agn.net/qrparci.html

Thanks Chuck!
